Notification Log MIB

Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes managed objects used for logging Simple Network Management Protocol (SNMP) Notifications.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119.

1. The SNMP Management Framework

The SNMP Management Framework presently consists of five major components:

- o An overall architecture, described in RFC 2571 [RFC2571].
- o Mechanisms for describing and naming objects and events for the purpose of management. The first version of this Structure of Management Information (SMI) is called SMIV1 and described in STD 16, RFC 1155 [RFC1155], STD 16, RFC 1212 [RFC1212] and RFC 1215 [RFC1215]. The second version, called SMIV2, is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].
- o Message protocols for transferring management information. The first version of the SNMP message protocol is called SNMPv1 and described in STD 15, RFC 1157 [RFC1157]. A second version of the SNMP message protocol, which is not an Internet standards track protocol, is called SNMPv2c and described in RFC 1901 [RFC1901] and RFC 1906 [RFC1906]. The third version of the message protocol is called SNMPv3 and described in RFC 1906 [RFC1906], RFC 2572 [RFC2572] and RFC 2574 [RFC2574].
- o Protocol operations for accessing management information. The first set of protocol operations and associated PDU formats is described in STD 15, RFC 1157 [RFC1157]. A second set of protocol operations and associated PDU formats is described in RFC 1905 [RFC1905].

- o A set of fundamental applications described in RFC 2573 [RFC2573] and the view-based access control mechanism described in RFC 2575 [RFC2575].

A more detailed introduction to the current SNMP Management Framework can be found in RFC 2570 [RFC2570].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the mechanisms defined in the SMI.

This memo specifies a MIB module that is compliant to the SMIV2. A MIB conforming to the SMIV1 can be produced through the appropriate translations. The resulting translated MIB must be semantically equivalent, except where objects or events are omitted because no translation is possible (use of Counter64). Some machine readable information in SMIV2 will be converted into textual descriptions in SMIV1 during the translation process. However, this loss of machine readable information is not considered to change the semantics of the MIB.

2. Overview

Systems that support SNMP often need a mechanism for recording Notification information as a hedge against lost Notifications, whether those are Traps or Informs [RFC1905] that exceed retransmission limits. This MIB therefore provides common infrastructure for other MIBs in the form of a local logging function. It is intended primarily for senders of Notifications but could be used also by receivers.

Given the Notification Log MIB, individual MIBs bear less responsibility to record the transient information associated with an event against the possibility that the Notification message is lost, and applications can poll the log to verify that they have not missed important Notifications.

2.1. Environment

The overall environmental concerns for the MIB are:

- o SNMP Engines and Contexts
- o Security

2.1.1. SNMP Engines and Contexts

There are two distinct information flows from multiple notification originators that one may log. The first is the notifications that are received (from one or more SNMP engines) for logging as SNMP informs and traps. The other comprises notifications delivered to an SNMP engine at the interface to the notification originator (using a notification mechanism other than SNMP informs or traps). The latter information flow (using a notification mechanism other than SNMP informs or traps) is modeled here as the SNMP engine (which maintains the log) sending a notification to itself. The remainder of this section discusses the handling of the former information flow - notifications (received in the form of SNMP informs or traps) from multiple SNMP engines.

As described in the SNMP architecture [RFC2571], a given system may support multiple SNMP engines operating independently of one another, each with its own SNMP engine identification. Furthermore, within the purview of a given engine there may be multiple named management contexts supporting overlapping or disjoint sets of MIB objects and Notifications. Thus, understanding a particular Notification requires knowing the SNMP engine and management context from whence it came.

To provide the necessary source information for a logged Notification, the MIB includes objects to record that Notification's source SNMP engine ID and management context name.

2.1.2. Security

Security for Notifications is awkward since access control for the objects in the Notification can be checked only where the Notification is created. Thus such checking is possible only for locally-generated Notifications, and even then only when security credentials are available.

For the purpose of this discussion, "security credentials" means the input values for the abstract service interface function `isAccessAllowed` [RFC2571] and using those credentials means conceptually using that function to see that those credentials allow access to the MIB objects in question, operating as for a Notification Originator in [RFC2573].

The Notification Log MIB has the notion of a "named log." By using log names and view-based access control [RFC2575] a network administrator can provide different access for different users. When an application creates a named log the security credentials of the creator stay associated with that log.

A managed system with fewer resources MAY disallow the creation of named logs, providing only the default, null-named log. Such a log has no implicit security credentials for Notification object access control and Notifications are put into it with no further checking.

When putting locally-generated Notifications into a named log, the managed system MUST use the security credentials associated with that log and MUST apply the same access control rules as described for a Notification Originator in [RFC2573].

The managed system SHOULD NOT apply access control when adding remotely-generated Notifications into either a named log or the default, null-named log. In those cases the security of the information in the log SHOULD be left to the normal, overall access control for the log itself.

The Notification Log MIB allows applications to set the maximum number of Notifications that can be logged, using `nlmConfigGlobalEntryLimit`. Similarly, an application can set the maximum age using `nlmConfigGlobalAgeOut`, after which older Notifications MAY be timed out. Please be aware that contention between multiple applications trying to set these objects to different values MAY affect the reliability and completeness of data seen by each application, i.e., it is possible that one application may change the value of either of these objects, resulting in some Notifications being deleted before the other applications have had a chance to see them. This could be used to orchestrate a denial-of-service attack. Methods for countering such an attack are for further study.

2.2. Structure

The MIB has the following sections:

- o Configuration -- control over how much the log can hold and what Notifications are to be logged.
- o Statistics -- indications of logging activity.
- o Log -- the Notifications themselves.

2.2.1. Configuration

The configuration section contains objects to manage resource use by the MIB.

This section also contains a table to specify what logs exist and how they operate. Deciding which Notifications are to be logged depends

on filters defined in the the `snmpNotifyFilterTable` in the standard SNMP Notification MIB [RFC2573] identified by the initial index (`snmpNotifyFilterName`) from that table.

2.2.2. Statistics

The statistics section contains counters for Notifications logged and discarded, supplying a means to understand the results of log capacity configuration and resource problems.

2.2.3. Log

The log contains the Notifications and the objects that came in their variable binding list, indexed by an integer that reflects when the entry was made. An application that wants to collect all logged Notifications or to know if it may have missed any can keep track of the highest index it has retrieved and start from there on its next poll, checking `sysUpTime` for a discontinuity that would have reset the index and perhaps have lost entries.

Variables are in a table indexed by Notification index and variable index within that Notification. The values are kept as a "discriminated union," with one value object per variable. Exactly which value object is instantiated depends on the SNMP data type of the variable, with a separate object of appropriate type for each distinct SNMP data type.

An application can thus reconstruct the information from the Notification PDU from what is recorded in the log.

2.3. Example

Following is an example configuration of a named log for logging only `linkUp` and `linkDown` Notifications.

In `nlmConfigLogTable`:

<code>nlmConfigLogFilterName.5."links"</code>	<code>= "link-status"</code>
<code>nlmConfigLogEntryLimit.5."links"</code>	<code>= 0</code>
<code>nlmConfigLogAdminStatus.5."links"</code>	<code>= enabled</code>
<code>nlmConfigLogOperStatus.5."links"</code>	<code>= operational</code>
<code>nlmConfigLogStorageType.5."links"</code>	<code>= nonVolatile</code>
<code>nlmConfigLogEntryStatus.5."links"</code>	<code>= active</code>

Note that `snmpTraps` is:

`iso.org.dod.internet.snmpV2.snmpModules.snmpMIB.snmpMIBObjects.5`

Or numerically:

1.3.6.1.6.3.1.1.5

And linkDown is snmpTraps.3 and linkUp is snmpTraps.4.

So to allow the two Notifications in snmpNotifyFilterTable:

```
snmpNotifyFilterMask.11."link-status".1.3.6.1.6.3.1.1.5.3 = 'H
snmpNotifyFilterType.11."link-status".1.3.6.1.6.3.1.1.5.3 = include
snmpNotifyFilterStorageType.11."link-status".1.3.6.1.6.3.1.1.5.3
= nonVolatile
snmpNotifyFilterRowStatus.11."link-status".1.3.6.1.6.3.1.1.5.3
= active

snmpNotifyFilterMask.11."link-status".1.3.6.1.6.3.1.1.5.4 = 'H
snmpNotifyFilterType.11."link-status".1.3.6.1.6.3.1.1.5.4 = include
snmpNotifyFilterStorageType.11."link-status".1.3.6.1.6.3.1.1.5.4
= nonVolatile
snmpNotifyFilterRowStatus.11."link-status".1.3.6.1.6.3.1.1.5.4
= active
```

nlmConfigGlobalEntryLimit OBJECT-TYPE

SYNTAX Unsigned32

MAX-ACCESS read-write

STATUS current

DESCRIPTION

"The maximum number of notification entries that may be held in nlmLogTable for all nlmLogNames added together. A particular setting does not guarantee that much data can be held.

If an application changes the limit while there are Notifications in the log, the oldest Notifications MUST be discarded to bring the log down to the new limit - thus the value of nlmConfigGlobalEntryLimit MUST take precedence over the values of nlmConfigGlobalAgeOut and nlmConfigLogEntryLimit, even if the Notification being discarded has been present for fewer minutes than the value of nlmConfigGlobalAgeOut, or if the named log has fewer entries than that specified in nlmConfigLogEntryLimit.

A value of 0 means no limit.

Please be aware that contention between multiple managers trying to set this object to different values MAY affect the reliability and completeness of data seen by each manager."

DEFVAL { 0 }

::= { nlmConfig 1 }

nlmConfigGlobalAgeOut OBJECT-TYPE

nlmLogTable OBJECT-TYPE

SYNTAX SEQUENCE OF NlmLogEntry

MAX-ACCESS not-accessible

STATUS current

DESCRIPTION

"A table of Notification log entries.

It is an implementation-specific matter whether entries in this table are preserved across initializations of the management system. In general one would expect that they are not.

Note that keeping entries across initializations of the management system leads to some confusion with counters and TimeStamps, since both of those are based on sysUpTime, which resets on management initialization. In this situation, counters apply only after the reset and nlmLogTime for entries made before the reset MUST be set to 0."

::= { nlmLog 1 }

nlmLogEntry OBJECT-TYPE

SYNTAX NlmLogEntry

MAX-ACCESS not-accessible

STATUS current

DESCRIPTION

"A Notification log entry.

Entries appear in this table when Notifications occur and pass filtering by nlmConfigLogFilterName and access control. They are removed to make way for new entries due to lack of resources or the values of nlmConfigGlobalEntryLimit, nlmConfigGlobalAgeOut, or nlmConfigLogEntryLimit.

If adding an entry would exceed nlmConfigGlobalEntryLimit or system resources in general, the oldest entry in any log SHOULD be removed to make room for the new one.

If adding an entry would exceed nlmConfigLogEntryLimit the oldest entry in that log SHOULD be removed to make room for the new one.

Before the managed system puts a locally-generated Notification into a non-null-named log it assures that the creator of the log has access to the information in the Notification. If not it does not log that Notification in that log."

    SYNTAX      INTEGER { counter32(1), unsigned32(2), timeTicks(3),
                        integer32(4), ipAddress(5), octetString(6),
                        objectId(7), counter64(8), opaque(9) }
    MAX-ACCESS  read-only
    STATUS      current
    DESCRIPTION
        "The type of the value. One and only one of the value
        objects that follow must be instantiated, based on this type."
    ::= { nmlLogVariableEntry 3 }

nmlLogVariableCounter32Val OBJECT-TYPE
    SYNTAX      Counter32
    MAX-ACCESS  read-only
    STATUS      current
    DESCRIPTION

```

"The value when nlmLogVariableType is 'counter32'."
::= { nlmLogVariableEntry 4 }

nlmLogVariableUnsigned32Val OBJECT-TYPE

SYNTAX Unsigned32
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"The value when nlmLogVariableType is 'unsigned32'."
::= { nlmLogVariableEntry 5 }

nlmLogVariableTimeTicksVal OBJECT-TYPE

SYNTAX TimeTicks
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"The value when nlmLogVariableType is 'timeTicks'."
::= { nlmLogVariableEntry 6 }

nlmLogVariableInteger32Val OBJECT-TYPE

SYNTAX Integer32
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"The value when nlmLogVariableType is 'integer32'."
::= { nlmLogVariableEntry 7 }

nlmLogVariableOctetStringVal OBJECT-TYPE

SYNTAX OCTET STRING
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"The value when nlmLogVariableType is 'octetString'."
::= { nlmLogVariableEntry 8 }

nlmLogVariableIpAddressVal OBJECT-TYPE

SYNTAX IpAddress
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"The value when nlmLogVariableType is 'ipAddress'.
Although this seems to be unfriendly for IPv6, we
have to recognize that there are a number of older
MIBs that do contain an IPv4 format address, known
as IpAddress.

IPv6 addresses are represented using TAddress or
InetAddress, and so the underlying datatype is

OCTET STRING, and their value would be stored in the nlmLogVariableOctetStringVal column."
 ::= { nlmLogVariableEntry 9 }

nlmLogVariableOidVal OBJECT-TYPE
 SYNTAX OBJECT IDENTIFIER
 MAX-ACCESS read-only
 STATUS current
 DESCRIPTION
 "The value when nlmLogVariableType is 'objectId'."

4. Intellectual Property

The IETF takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on the IETF's procedures with respect to rights in standards-track and standards-related documentation can be found in BCP-11. Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementors or users of this specification can be obtained from the IETF Secretariat.

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights which may cover technology that may be required to practice this standard. Please address the information to the IETF Executive Director.
