**Guidelines on the Cryptographic Algorithms to  
Accompany the Usage of Standards GOST R 34.10-2012 and GOST R 34.11-2012**

**Abstract**

The purpose of this document is to make the specifications of the cryptographic algorithms defined by the Russian national standards GOST R 34.10-2012 and GOST R 34.11-2012 available to the Internet community for their implementation in the cryptographic protocols based on the accompanying algorithms.

These specifications define the pseudorandom functions, the key agreement algorithm based on the Diffie-Hellman algorithm and a hash function, the parameters of elliptic curves, the key derivation functions, and the key export functions.

**Status of This Memo**

This document is not an Internet Standards Track specification; it is published for informational purposes.

This is a contribution to the RFC Series, independently of any other RFC stream. The RFC Editor has chosen to publish this document at its discretion and makes no statement about its value for implementation or deployment. Documents approved for publication by the RFC Editor are not a candidate for any level of Internet Standard; see Section 2 of RFC 5741.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at <http://www.rfc-editor.org/info/rfc7836>.

## 1. Introduction

The accompanying algorithms are intended for the implementation of cryptographic protocols. This memo contains a description of the accompanying algorithms based on the Russian national standards GOST R 34.10-2012 [GOST3410-2012] and GOST R 34.11-2012 [GOST3411-2012]. The English versions of these standards can be found in [RFC7091] and [RFC6986]; the English version of the encryption standard GOST 28147-89 [GOST28147-89] (which is used in the key export functions) can be found in [RFC5830].

The specifications of algorithms and parameters proposed in this memo are provided on the basis of experience in the development of the cryptographic protocols, as described in [RFC4357], [RFC4490], and [RFC4491].

This memo describes the pseudorandom functions, the key agreement algorithm based on the Diffie-Hellman algorithm and a hash function, the parameters of elliptic curves, the key derivation functions, and the key export functions necessary to ensure interoperability of security protocols that make use of the Russian cryptographic standards GOST R 34.10-2012 [GOST3410-2012] digital signature algorithm and GOST R 34.11-2012 [GOST3411-2012] cryptographic hash function.

## 2. Conventions Used in This Document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

## 3. Basic Terms, Definitions, and Notations

This document uses the following terms and definitions for the sets and operations on the elements of these sets:

(xor) Exclusive-or of two binary vectors of the same length.

$V_n$  The finite vector space over  $GF(2)$  of dimension  $n$ ,  $n \geq 0$ , with the (xor) operation. For  $n = 0$ , the  $V_0$  space consists of a single empty element of size 0. If  $U$  is an element of  $V_n$ , then  $U = (u_{(n-1)}, u_{(n-2)}, \dots, u_1, u_0)$ , where  $u_i \in \{0, 1\}$ .

$V_8(r)$

The set of byte vectors of size  $r$ ,  $r \geq 0$ , for  $r = 0$  the  $V_8(r)$  set consists of a single empty element of size 0. If  $W$  is an element of  $V_8(r)$ ,  $r > 0$ , then  $W = (w^0, w^1, \dots, w^{(r-1)})$ , where  $w^0, w^1, \dots, w^{(r-1)}$  are elements of  $V_8$ .

Bit representation

The bit representation of the element  $W = (w^0, w^1, \dots, w^{(r-1)})$  of  $V_8(r)$  is an element  $(w_{(8r-1)}, w_{(8r-2)}, \dots, w_1, w_0)$  of  $V_{(8 \times r)}$ , where  $w^0 = (w_7, w_6, \dots, w_0)$ ,  $w^1 = (w_{15}, w_{14}, \dots, w_8)$ ,  $\dots$ ,  $w^{(r-1)} = (w_{(8r-1)}, w_{(8r-2)}, \dots, w_{(8r-8)})$  are elements of  $V_8$ .

Byte representation

If  $n$  is a multiple of 8,  $r = n/8$ , then the byte representation of the element  $W = (w_{(n-1)}, w_{(n-2)}, \dots, w_0)$  of  $V_n$  is a byte vector  $(w^0, w^1, \dots, w^{(r-1)})$  of  $V_8(r)$ , where  $w^0 = (w_7, w_6, \dots, w_0)$ ,  $w^1 = (w_{15}, w_{14}, \dots, w_8)$ ,  $\dots$ ,  $w^{(r-1)} = (w_{(8r-1)}, w_{(8r-2)}, \dots, w_{(8r-8)})$  are elements of  $V_8$ .

$A|B$

Concatenation of byte vectors  $A$  and  $B$ , i.e., if  $A$  in  $V_8(r_1)$ ,  $B$  in  $V_8(r_2)$ ,  $A = (a^0, a^1, \dots, a^{(r_1-1)})$  and  $B = (b^0, b^1, \dots, b^{(r_2-1)})$ , then  $A|B = (a^0, a^1, \dots, a^{(r_1-1)}, b^0, b^1, \dots, b^{(r_2-1)})$  is an element of  $V_8(r_1+r_2)$ .

$K$  (key) An arbitrary element of  $V_n$ . If  $K$  in  $V_n$ , then its size (in bits) is equal to  $n$ , where  $n$  can be an arbitrary natural number.

This memo uses the following abbreviations and symbols:

Symbols	Meaning
H_256	GOST R 34.11-2012 hash function with 256-bit output
H_512	GOST R 34.11-2012 hash function with 512-bit output
HMAC	Hashed-based Message Authentication Code. A function for calculating a message authentication code, based on a hash function in accordance with [RFC2104]
PRF	A pseudorandom function, i.e., a transformation that allows generation of a pseudorandom sequence of bytes
KDF	A key derivation function, i.e., a transformation that allows keys and keying material to be derived from the root key and additional input using a pseudorandom function
VKO	A key agreement algorithm based on the Diffie-Hellman algorithm and a hash function

To generate a byte sequence of the size  $r$  with functions that give a longer output, the output is truncated to the first  $r$  bytes. This remark applies to the following functions:

- o the functions described in Section 4.2;
- o KDF\_TREE\_GOSTR3411\_2012\_256 described in Section 4.4;
- o KDF\_GOSTR3411\_2012\_256 described in Section 4.5.

Hereinafter, all data are provided in byte representation unless otherwise specified.

If a function is defined outside this document (e.g., H\_256) and its definition requires arguments in bit representation, it is assumed that the bit representations of the arguments are formed immediately before the calculation of the function (in particular, immediately after the application of the operation ( $|$ ) to the byte representation of the arguments).

If the output of another function defined outside of this document is used as an argument of the functions defined below and it has the bit representation, then it is assumed that an output **MUST** have a length

that is a multiple of 8 and that it will be translated into the byte representation in advance.

When a point on an elliptic curve is given to an input of a hash function, affine coordinates for short Weierstrass form are used (see Section 5): an x coordinate value is fed first, a y coordinate value is fed second, both in little-endian format.

## 4. Algorithm Descriptions

### 4.1. HMAC Functions

This section defines the HMAC transformations based on the GOST R 34.11-2012 [GOST3411-2012] algorithm.

#### 4.1.1. HMAC\_GOSTR3411\_2012\_256

This HMAC transformation is based on the GOST R 34.11-2012 [GOST3411-2012] hash function with 256-bit output. The object identifier of this transformation is shown below:

```
id-tc26-hmac-gost-3411-12-256::= {iso(1) member-body(2) ru(643)
rosstandart(7) tc26(1) algorithms(1) mac(4) hmac-gost-
3411-12-256(1)}.
```

This algorithm uses H\_256 as a hash function for HMAC, described in [RFC2104]. The method of forming the values of ipad and opad is also specified in [RFC2104]. The size of HMAC\_GOSTR3411\_2012\_256 output is equal to 32 bytes, the block size of the iterative procedure for the H\_256 compression function is equal to 64 bytes (in the notation of [RFC2104], L = 32 and B = 64, respectively).

#### 4.1.2. HMAC\_GOSTR3411\_2012\_512

This HMAC transformation is based on the GOST R 34.11-2012 [GOST3411-2012] hash function with 512-bit output. The object identifier of this transformation is shown below:

```
id-tc26-hmac-gost-3411-12-512::= {iso(1) member-body(2) ru(643)
rosstandart(7) tc26(1) algorithms(1) mac(4) hmac-gost-
3411-12-512(2)}.
```

This algorithm uses H\_512 as a hash function for HMAC, described in [RFC2104]. The method of forming the values of ipad and opad is also specified in [RFC2104]. The size of HMAC\_GOSTR3411\_2012\_512 output is equal to 64 bytes, the block size of the iterative procedure for the H\_512 compression function is equal to 64 bytes (in the notation of [RFC2104], L = 64 and B = 64, respectively).

## 4.2. Pseudorandom Functions

This section defines four HMAC-based PRF transformations recommended for usage. Two of them are designed for the Transport Layer Security (TLS) protocol and two are designed for the IPsec protocol.

### 4.2.1. PRFs for the TLS Protocol

#### 4.2.1.1. PRF\_TLS\_GOSTR3411\_2012\_256

This is the transformation providing the pseudorandom function for the TLS protocol (1.0 and higher versions) in accordance with GOST R 34.11-2012 [GOST3411-2012]. It uses the P\_GOSTR3411\_2012\_256 function that is similar to the P\_hash function defined in Section 5 of [RFC5246], where the HMAC\_GOSTR3411\_2012\_256 function (defined in Section 4.1.1 of this document) is used as the HMAC\_hash function.

$$\text{PRF\_TLS\_GOSTR3411\_2012\_256}(\text{secret}, \text{label}, \text{seed}) = \\ = \text{P\_GOSTR3411\_2012\_256}(\text{secret}, \text{label} \parallel \text{seed}).$$

Label and seed values MUST be assigned by a protocol, their lengths SHOULD be fixed by a protocol in order to avoid possible collisions.

#### 4.2.1.2. PRF\_TLS\_GOSTR3411\_2012\_512

This is the transformation providing the pseudorandom function for the TLS protocol (1.0 and higher versions) in accordance with GOST R 34.11-2012 [GOST3411-2012]. It uses the P\_GOSTR3411\_2012\_512 function that is similar to the P\_hash function defined in Section 5 of [RFC5246], where the HMAC\_GOSTR3411\_2012\_512 function (defined in Section 4.1.2 of this document) is used as the HMAC\_hash function.

$$\text{PRF\_TLS\_GOSTR3411\_2012\_512}(\text{secret}, \text{label}, \text{seed}) = \\ = \text{P\_GOSTR3411\_2012\_512}(\text{secret}, \text{label} \parallel \text{seed}).$$

Label and seed values MUST be assigned by a protocol, their lengths SHOULD be fixed by a protocol in order to avoid possible collisions.

### 4.2.2. PRFs for the IKEv2 Protocol Based on GOST R 34.11-2012

The specification for the Internet Key Exchange protocol version 2 (IKEv2) [RFC7296] defines the usage of PRFs in various parts of the protocol for the purposes of generating and authenticating keying material.

IKEv2 has no default PRF. This document specifies that HMAC\_GOSTR3411\_2012\_256 may be used as the "prf" function in the "prf+" function for the IKEv2 protocol

(PRF\_IPSEC\_PRFLPLUS\_GOSTR3411\_2012\_256). Also, this document specifies that HMAC\_GOSTR3411\_2012\_512 may be used as the "prf" function in the "prf+" function for the IKEv2 protocol (PRF\_IPSEC\_PRFLPLUS\_GOSTR3411\_2012\_512).

#### 4.3. VKO Algorithms for Key Agreement

This section specifies the key agreement algorithms based on GOST R 34.10-2012 [GOST3410-2012].

##### 4.3.1. VKO\_GOSTR3410\_2012\_256

The VKO\_GOSTR3410\_2012\_256 transformation is used for agreement of 256-bit keys and is based on the 256-bit version of GOST R 34.11-2012 [GOST3411-2012]. This algorithm can be applied for a key agreement using GOST R 34.10-2012 [GOST3410-2012] with 256-bit or 512-bit private keys.

The algorithm is designed to produce an encryption key or a keying material of size 256 bits to be used in various cryptographic protocols. A key or a keying material KEK\_VKO (x, y, UKM) is produced from the private key x of one side, the public key y\*P of the opposite side and the User Keying Material (UKM) value.

The algorithm can be used for static and ephemeral keys with the public key size  $n \geq 512$  bits including the case where one side uses a static key and the other uses an ephemeral one.

The UKM parameter is optional (the default UKM = 1) and can take any integer value from 1 to  $2^{(n/2)}-1$ . It is allowed to use a non-zero UKM of an arbitrary size that does not exceed  $n/2$  bits. If at least one of the parties uses static keys, the RECOMMENDED length of UKM is 64 bits or more.

KEK\_VKO (x, y, UKM) is calculated using the formulas:

$$\text{KEK\_VKO} (x, y, \text{UKM}) = \text{H\_256} (K (x, y, \text{UKM})),$$

$$K (x, y, \text{UKM}) = (m/q * \text{UKM} * x \bmod q) * (y * P),$$

where m and q are the parameters of an elliptic curve defined in the GOST R 34.10-2012 [GOST3411-2012] standard (m is an elliptic curve points group order, q is an order of a cyclic subgroup), P is a non-zero point of the subgroup; P is defined by a protocol.

This algorithm is defined similar to the one specified in Section 5.2 of [RFC4357], but applies the hash function H\_256 instead of the hash function GOST R 34.11-94 [GOST3411-94] (referred to as "gostR3411").

In addition,  $K(x, y, UKM)$  is calculated with public key size  $n \geq 512$  bits and UKM has a size up to  $n/2$  bits.

#### 4.3.2. VKO\_GOSTR3410\_2012\_512

The VKO\_GOSTR3410\_2012\_512 transformation is used for agreement of 512-bit keys and is based on the 512-bit version of GOST R 34.11-2012 [GOST3411-2012]. This algorithm can be applied for a key agreement using GOST R 34.10-2012 [GOST3410-2012] with 512-bit private keys.

The algorithm is designed to produce an encryption key or a keying material of size 512 bits to be used in various cryptographic protocols. A key or a keying material  $KEK\_VKO(x, y, UKM)$  is produced from the private key  $x$  of one side, the public key  $y \cdot P$  of the opposite side and the UKM value, considered as an integer.

The algorithm can be used for static and ephemeral keys with the public key size  $n \geq 1024$  bits including the case where one side uses a static key and the other uses an ephemeral one.

The UKM parameter is optional (the default  $UKM = 1$ ) and can take any integer value from 1 to  $2^{(n/2)} - 1$ . It is allowed to use a non-zero UKM of an arbitrary size that does not exceed  $n/2$  bits. If at least one of the parties uses static keys, the RECOMMENDED length of UKM is 128 bits or more.

$KEK\_VKO(x, y, UKM)$  is calculated using the formulas:

$$KEK\_VKO(x, y, UKM) = H_{512}(K(x, y, UKM)),$$

$$K(x, y, UKM) = (m/q * UKM * x \bmod q) * (y * P),$$

where  $m$  and  $q$  are the parameters of an elliptic curve defined in the GOST R 34.10-2012 [GOST3411-2012] standard ( $m$  is an elliptic curve points group order,  $q$  is an order of a cyclic subgroup),  $P$  is a non-zero point of the subgroup;  $P$  is defined by a protocol.

This algorithm is defined similar to the one specified in Section 5.2 of [RFC4357], but applies the hash function  $H_{512}$  instead of the hash function GOST R 34.11-94 [GOST3411-94] (referred to as "gostR3411"). In addition,  $K(x, y, UKM)$  is calculated with public key size  $n \geq 1024$  bits and UKM has a size up to  $n/2$  bits.

#### 4.4. The Key Derivation Function KDF\_TREE\_GOSTR3411\_2012\_256

The key derivation function KDF\_TREE\_GOSTR3411\_2012\_256 based on the HMAC\_GOSTR3411\_2012\_256 function is given by:

$$\text{KDF\_TREE\_GOSTR3411\_2012\_256}(K_{\text{in}}, \text{label}, \text{seed}, R) = K(1) \mid K(2) \mid K(3) \mid K(4) \mid \dots,$$

$$K(i) = \text{HMAC\_GOSTR3411\_2012\_256}(K_{\text{in}}, [i]_{\text{b}} \mid \text{label} \mid 0x00 \mid \text{seed} \mid [L]_{\text{b}}), i \geq 1,$$

where:

**K<sub>in</sub>** Derivation key.

**label, seed**

The parameters that MUST be assigned by a protocol; their lengths SHOULD be fixed by a protocol.

**R** A fixed external parameter, with possible values of 1, 2, 3, or 4.

**i** Iteration counter.

**[i]<sub>b</sub>** Byte representation of the iteration counter (in the network byte order); the number of bytes in the representation [i]<sub>b</sub> is equal to R (no more than 4 bytes).

**L** The required size (in bits) of the generated keying material (an integer, not exceeding  $256 \cdot (2^{(8 \cdot R)} - 1)$ ).

**[L]<sub>b</sub>** Byte representation of L, in network byte order (variable length: no leading zero bytes added).

The key derivation function KDF\_TREE\_GOSTR3411\_2012\_256 is intended for generating a keying material of size L, not exceeding  $256 \cdot (2^{(8 \cdot R)} - 1)$  bits, and utilizing general principles of the input and output for the key derivation function outlined in Section 5.1 of NIST SP 800-108 [NISTSP800-108]. The HMAC\_GOSTR3411\_2012\_256 algorithm described in Section 4.1.1 is selected as a pseudorandom function.

Each key derived from the keying material formed using the derivation key K<sub>in</sub> (0-level key) may be a 1-level derivation key and may be used to generate a new keying material. The keying material derived from the first level derivation key can be split down into the second level derivation keys. The application of this procedure leads to the construction of the key tree with the root key and the formation

of the keying material to the hierarchy of the levels, as described in Section 6 of NIST SP 800-108 [NISTSP800-108]. The partitioning procedure for keying material at each level is defined in accordance with a specific protocol.

#### 4.5. The Key Derivation Function KDF\_GOSTR3411\_2012\_256

The KDF\_GOSTR3411\_2012\_256 function is equivalent to the function KDF\_TREE\_GOSTR3411\_2012\_256, when  $R = 1$ ,  $L = 256$ , and is given by:

$$\text{KDF\_GOSTR3411\_2012\_256}(K_{\text{in}}, \text{label}, \text{seed}) = \text{HMAC\_GOSTR3411\_2012\_256}(K_{\text{in}}, 0x01 \mid \text{label} \mid 0x00 \mid \text{seed} \mid 0x01 \mid 0x00),$$

where:

$K_{\text{in}}$  Derivation key.

label, seed

The parameters that MUST be assigned by a protocol; their lengths SHOULD be fixed by a protocol.

#### 4.6. Key Wrap and Key Unwrap

Wrapped representation of a secret key  $K$  (256-bit GOST 28147-89 [GOST28147-89] key, 256-bit or 512-bit GOST R 34.10-2012 [GOST3410-2012] private key) is formed as follows by using a given export key  $K_e$  (GOST 28147-89 [GOST28147-89] key) and a random seed vector:

1. Generate a random seed vector from 8 up to 16 bytes.
2. With the key derivation function, using an export key  $K_e$  as a derivation key, produce a key  $\text{KEK}_e(K_e, \text{seed})$ , where:

$$\text{KEK}_e(K_e, \text{seed}) = \text{KDF\_GOSTR3411\_2012\_256}(K_e, \text{label}, \text{seed}),$$

where the KDF\_GOSTR3411\_2012\_256 function (see Section 4.5) is used as a key derivation function for the fixed label value

$$\text{label} = (0x26 \mid 0xBD \mid 0xB8 \mid 0x78).$$

3. GOST 28147-89 [GOST28147-89] Message Authentication Code (MAC) value (4-byte) for the data  $K$  and the key  $\text{KEK}_e(K_e, \text{seed})$  is calculated; the initialization vector (IV) in this case is equal to the first 8 bytes of seed. The resulting value is denoted as  $\text{CEK\_MAC}$ .

4. The key  $K$  is encrypted with the GOST 28147-89 [GOST28147-89] algorithm in the Electronic Codebook (ECB) mode with the key  $KEK_e(K_e, \text{seed})$ . The result is denoted as  $CEK\_ENC$ .
5. The wrapped representation of the key is  $(\text{seed} \mid CEK\_ENC \mid CEK\_MAC)$ .

The value of key  $K$  is restored from the wrapped representation of the key and the export key  $K_e$  as follows:

1. Obtain the seed,  $CEK\_ENC$  and  $CEK\_MAC$  values from the wrapped representation of the key.
2. With the key derivation function, using the export key  $K_e$  as a derivation key, produce a key  $KEK_e(K_e, \text{seed})$ , where:

$$KEK_e(K_e, \text{seed}) = KDF\_GOSTR3411\_2012\_256(K_e, \text{label}, \text{seed}),$$

where the  $KDF\_GOSTR3411\_2012\_256$  function (see Section 4.5) is used as a key derivation function for the fixed label value

$$\text{label} = (0x26 \mid 0xBD \mid 0xB8 \mid 0x78).$$

3. The  $CEK\_ENC$  field is decrypted with the GOST 28147-89 [GOST28147-89] algorithm in the Electronic Codebook (ECB) mode with the key  $KEK_e(K_e, \text{seed})$ . The unwrapped key  $K$  is assumed to be equal to the result of decryption.
4. GOST 28147-89 [GOST28147-89] MAC value (4-byte) for the data  $K$  and the key  $KEK_e(K_e, \text{seed})$  is calculated; the initialization vector (IV) in this case is equal to the first 8 bytes of seed. If the result is not equal to  $CEK\_MAC$ , an error is returned.

The GOST 28147-89 [GOST28147-89] algorithm is used with the parameter set defined in Appendix C of this document.

## 5. The Parameters of Elliptic Curves

This section defines the elliptic curves parameters and object identifiers that are RECOMMENDED for usage with the signature and verification algorithms of the digital signature in accordance with the GOST R 34.10-2012 [GOST3410-2012] standard and with the key agreement algorithms  $VK0\_GOSTR3410\_2012\_256$  and  $VK0\_GOSTR3410\_2012\_512$ .

This document does not negate the use of other parameters of elliptic curves.

## 5.1. Canonical Form

This section defines the elliptic curves parameters of the GOST R 34.10-2012 [GOST3410-2012] standard for the case of elliptic curves with prime 512-bit moduli in canonical (short Weierstrass) form, that is given by the following equation defined in GOST R 34.10-2012 [GOST3410-2012]:

$$y^2 = x^3 + ax + b \pmod{p}.$$

In case of elliptic curves with 256-bit prime moduli, the parameters defined in [RFC4357] are proposed for use.

### 5.1.1. Parameters and Object Identifiers

The parameters for each elliptic curve are represented by the following values, which are defined in GOST R 34.10-2012 [GOST3410-2012]:

- p the characteristic of the underlying prime field;
- a, b the coefficients of the equation of the elliptic curve in the canonical form;
- m the elliptic curve group order;
- q the elliptic curve subgroup order;
- (x, y) the coordinates of the point P (generator of the subgroup of order q) of the elliptic curve in the canonical form.

Both sets of the parameters are presented as structures of the form:

```
SEQUENCE {  
  p    INTEGER,  
  a    INTEGER,  
  b    INTEGER,  
  m    INTEGER,  
  q    INTEGER,  
  x    INTEGER,  
  y    INTEGER  
}
```

The parameter sets have the following object identifiers:

1. id-tc26-gost-3410-12-512-paramSetA ::= {iso(1) member-body(2) ru(643) rosstandart(7) tc26(1) constants(2) sign-constants(1) gost-3410-12-512-constants(2) paramSetA(1)};

2. `id-tc26-gost-3410-12-512-paramSetB := {iso(1) member-body(2)  
ru(643) rosstandart(7) tc26(1) constants(2) sign-constants(1)  
gost-3410-12-512-constants(2) paramSetB(2)}`.

The corresponding values of the parameter sets can be found in Appendix A.1.

## 5.2. Twisted Edwards Form

This section defines the elliptic curves parameters and object identifiers of the GOST R 34.10-2012 [GOST3410-2012] standard for the case of elliptic curves that have a representation in the twisted Edwards form with prime 256-bit and 512-bit moduli.

A twisted Edwards curve  $E$  over a finite prime field  $F_p$ ,  $p > 3$ , is an elliptic curve defined by the equation:

$$e \cdot u^2 + v^2 = 1 + d \cdot u^2 \cdot v^2 \pmod{p},$$

where  $e, d$  are in  $F_p$ ,  $ed(e-d) \neq 0$ .

A twisted Edwards curve has an equivalent representation in the short Weierstrass form defined by parameters  $a, b$ . The parameters  $a, b, e$ , and  $d$  are related as follows:

$$\begin{aligned} a &= s^2 - 3 \cdot t^2 \pmod{p}, \\ b &= 2 \cdot t^3 - t \cdot s^2 \pmod{p}, \end{aligned}$$

where:

$$\begin{aligned} s &= (e - d)/4 \pmod{p}, \\ t &= (e + d)/6 \pmod{p}. \end{aligned}$$

Coordinate transformations are defined as follows:

$$\begin{aligned} (u, v) &\rightarrow (x, y) = (s(1 + v)/(1 - v) + t, s(1 + v)/((1 - v)u)), \\ (x, y) &\rightarrow (u, v) = ((x - t)/y, (x - t - s)/(x - t + s)). \end{aligned}$$

### 5.2.1. Parameters and Object Identifiers

The parameters for each elliptic curve are represented by the following values, which are defined in GOST R 34.10-2012 [GOST3410-2012]:

- $p$       The characteristic of the underlying prime field.
- $a, b$     The coefficients of the equation of the elliptic curve in the canonical form.

- e, d**      The coefficients of the equation of the elliptic curve in the twisted Edwards form.
- m**        The elliptic curve group order.
- q**        The elliptic curve subgroup order.
- (x, y)**    The coordinates of the point P (generator of the subgroup of order q) of the elliptic curve in the canonical form.
- (u, v)**    The coordinates of the point P (generator of the subgroup of order q) of the elliptic curve in the twisted Edwards form.

Both sets of the parameters are presented as ASN structures of the form:

```
SEQUENCE {  
  p      INTEGER,  
  a      INTEGER,  
  b      INTEGER,  
  e      INTEGER,  
  d      INTEGER,  
  m      INTEGER,  
  q      INTEGER,  
  x      INTEGER,  
  y      INTEGER,  
  u      INTEGER,  
  v      INTEGER  
}
```

The parameter sets have the following object identifiers:

1. `id-tc26-gost-3410-2012-256-paramSetA ::= {iso(1) member-body(2) ru(643) rosstandart(7) tc26(1) constants(2) sign-constants(1) gost-3410-12-256-constants(1) paramSetA(1)};`
2. `id-tc26-gost-3410-2012-512-paramSetC ::= {iso(1) member-body(2) ru(643) rosstandart(7) tc26(1) constants(2) sign-constants(1) gost-3410-12-512-constants(2) paramSetC(3)}.`

The corresponding values of the parameter sets can be found in Appendix A.2.

## 6. Security Considerations

This entire document is about security considerations.

## Appendix C. GOST 28147-89 Parameter Set

The parameter set has the following object identifier:

```
id-tc26-gost-28147-param-Z:= {iso(1) member-body(2) ru(643)
rosstandart(7) tc26(1) constants(2) cipher-constants(5)
gost-28147-constants(1) param-Z(1)}
```

The parameter set is defined below:

x	K1(x)	K2(x)	K3(x)	K4(x)	K5(x)	K6(x)	K7(x)	K8(x)
0	c	6	b	c	7	5	8	1
1	4	8	3	8	f	d	e	7
2	6	2	5	2	5	f	2	e
3	2	3	8	1	a	6	5	d
4	a	9	2	d	8	9	6	0
5	5	a	f	4	1	2	9	5
6	b	5	a	f	6	c	1	8
7	9	c	d	6	d	a	c	3
8	e	1	e	7	0	b	f	4
9	8	e	1	0	9	7	4	f
a	d	4	7	a	3	8	b	a
b	7	7	4	5	e	1	0	6
c	0	b	c	3	b	4	d	9
d	3	d	9	e	4	3	a	c
e	f	0	6	9	2	e	3	b
f	1	f	0	b	c	0	7	2

## Acknowledgments

We thank Valery Smyslov, Igor Ustinov, Basil Dolmatov, Russ Housley, Dmitry Khovratovich, Oleksandr Kazymyrov, Ekaterina Smyshlyaeva, Vasily Nikolaev, and Lolita Sonina for their careful readings and useful comments.
