## PPP Over FUNI

### Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

### Abstract

The Point-to-Point Protocol (PPP) [1] provides a standard method for transporting multi-protocol datagrams over point-to-point links.

This document describes the use of ATM Frame User Network Interface (FUNI) for framing PPP encapsulated packets.

### Applicability

This specification is intended for those implementations which desire to use the facilities which are defined for PPP, such as the Link Control Protocol, Network-layer Control Protocols, authentication, and compression. These capabilities require a point-to-point relationship between the peers, and are not designed for the multi-point relationships which are available in ATM and other multi-access environments.

## 1. Introduction

ATM FUNI protocol is designed to provide virtual connections between end stations attached to the same network. These connections offer a packet delivery service that includes error detection, but does not do error correction.

Most existing implementations of PPP use ISO 3309 HDLC as a basis for their framing [3].

When an ATM network is configured with point-to-point connections, PPP can use FUNI as a framing mechanism.

## 2. Conventions

The keywords **MUST**, **MUST NOT**, **REQUIRED**, **SHALL**, **SHALL NOT**, **SHOULD**, **SHOULD NOT**, **RECOMMENDED**, **MAY**, and **OPTIONAL**, when they appear in this document, are to be interpreted as described in [10].

## 3. FUNI Layer Service Interface

The PPP layer treats the underlying ATM FUNI layer service as a bit-synchronous point-to-point link. In this context, the PPP link corresponds to an ATM FUNI virtual connection. The virtual connection **MUST** be full-duplex, point to point, and it **MAY** be either dedicated (i.e. permanent, set up by provisioning) or switched (set up on demand). In addition, the PPP/FUNI service interface boundary **MUST** meet the following requirements:

**Interface Format** - The PPP/FUNI layer boundary presents an octet service interface to the FUNI layer. There is no provision for sub-octets to be supplied or accepted.

**Transmission Rate** - The PPP layer does not impose any restrictions regarding transmission rate or the underlying ATM layer traffic descriptor parameters.

**Control Signals** - The FUNI layer **MUST** provide control signals to the PPP layer which indicate when the virtual connection link has become connected or disconnected. These provide the "Up" and

"Down" events to the LCP state machine [1] within the PPP layer.

#### 4. Multi-Protocol Encapsulation

This specification uses the principles, terminology, and frame structure described in "Multiprotocol Encapsulation over ATM Adaptation Layer 5" [4].

The purpose of this specification is not to document what is already standardized in [4], but to specify how the mechanisms described in [4] are to be used to map PPP onto a FUNI-based ATM network. Section 1 within [4] defines the two mechanisms for identifying the Protocol Data Unit (PDU) payload field's protocol type: virtual circuit based multiplexing, and Logical Link Control (LLC) encapsulation. In the former technique, the payload's protocol type is implicitly agreed to by the end points for each virtual circuit using provisioning or control plane procedures. When using the LLC encapsulation technique, the payload's protocol type is explicitly identified on a per PDU basis by an in-band LLC header, followed by the payload data.

When transporting a PPP payload over FUNI, an implementation:

1. MUST support virtual circuit multiplexed PPP payloads as described in section 5 below by mutual configuration or negotiation of both end points. This technique is referred to as "VC-multiplexed PPP".
2. MUST support LLC encapsulated PPP payloads on PVCs as described in section 6 below by mutual configuration or negotiation of both end points. This technique is referred to as "LLC encapsulated PPP".
3. For SVC set up, an implementation MUST negotiate using the Q.2931 [9] Annex C procedure, encoding the Broadband Lower Layer Interface (B-LLI) information element to signal either VC-multiplexed PPP or LLC encapsulated PPP. The details of this control plane procedure are described in section 7.

If an implementation is connecting through a Frame Relay/ATM FRF.8 [7] service inter-working unit to an RFC 1973 [6] end point, then it MUST use LLC encapsulated PPP payloads. Frame Relay/ATM FRF.8 inter-working units are exempted from the requirement to support VC-multiplexed PPP. This exemption allows the FR/ATM IWU to remain compliant with FRF.8 when the PPP over FUNI end point is inter-operating with an RFC 1973 end point.

#### 5. Virtual Circuit Multiplexed PPP Over FUNI

The FUNI protocol data unit (PDU) format [2] is as follows:

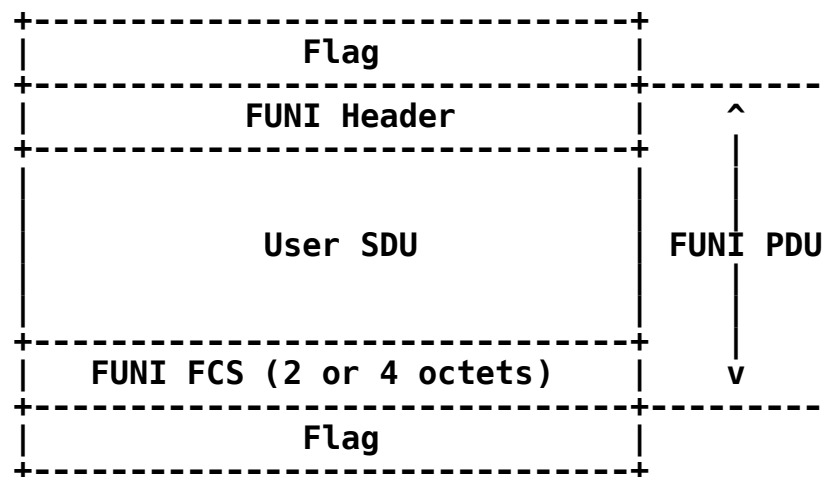

Figure 1

The FUNI Header includes a 10-bit or 24-bit Frame Address (a.k.a. VPI/VCI bits), a Congestion Notification bit, a Congestion Loss Priority bit, and four Reserved bits.

The User SDU field contains user information up to 4096 (optionally up to 64K) octets.

The FCS field protects the entire FUNI PDU except for the FCS field itself.

A VC-multiplexed PPP frame SHALL constitute the User Service Data Unit (SDU) field and is defined as shown in figure 2:

Figure 2

Each of these fields are specifically defined in [1].

## 6. LLC Encapsulated PPP Over FUNI

LLC encapsulated PPP over FUNI is the alternative technique to VC-multiplexed PPP over FUNI.

The FUNI SDU payload field is encoded as shown in figure 3. The pertinent fields in that diagram are:

1. LLC header: 2 bytes encoded to specify a source SAP and destination SAP of routed OSI PDU (values 0xFE 0xFE), followed by an Un-numbered Information (UI) frame type (value 0x03).
2. Network Layer Protocol Identifier (NLPID) representing PPP, (value 0xCF).
3. the PPP protocol identifier field, which can be either 1 or 2 octets long. See reference [1].
4. followed by the PPP information field as per Figure 2.

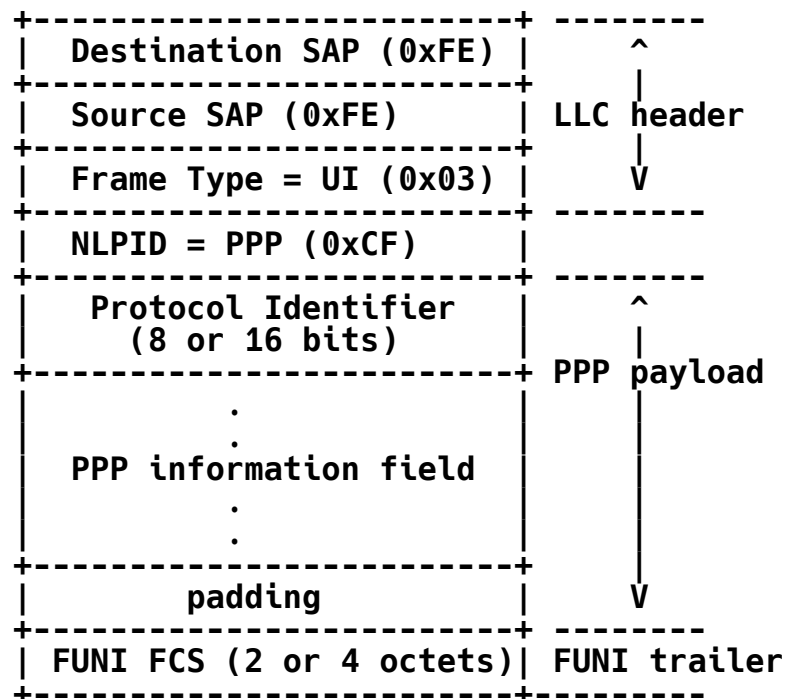

Figure 3

The end points MAY be bi-laterally provisioned to send other LLC-encapsulated protocols besides PPP across the same virtual connection. However, they MUST NOT send packets belonging to any protocol that has an active NCP within the PPP session. Implementations SHOULD do packet scheduling that minimizes the performance impact on the quality of service commitments associated with both the LLC-encapsulated PPP and non-PPP protocol flows.

## 7. Out-Of-Band Control Plane Signaling

When originating a switched virtual circuit FUNI connection, the caller **MUST** request in the SETUP message either VC-multiplexed PPP, LLC-encapsulated PPP, or else both VC-multiplexed and LLC-encapsulated PPP. When a caller is offering both techniques, the two B-LLI IEs are encoded within a Broadband Repeat Indicator IE in the order of their preference. The called implementation **MUST** be able to accept an incoming call that offers LLC-encapsulated PPP in the caller's request. The called implementation **MUST** reject a call set up request that only offers an encapsulation that it does not support. Implementations originating a call offering both protocol encapsulation techniques **MUST** be able to negotiate the use of LLC-encapsulated PPP.

When originating a virtual circuit multiplexed call that is to carry a PPP payload, the ITU Q.2931 [9] B-LLI element user information layer 3 protocol field is encoded to select ISO/IEC TR 9577 [5] in octet 7. The extension octets specify an IPI value of PPP (0xCF). By definition, the first bytes of the FUNI frame's payload field will always contain a PPP header followed by a packet.

When originating an LLC encapsulated call that is to carry a PPP payload, the ITU Q.2931 B-LLI element user information layer 2 protocol field is encoded to select LAN Logical Link Control (ISO/IEC8802-2) in octet 6. See RFC 1755 [8] appendix A for an example. By definition, the first bytes of the FUNI frame's payload field will contain an LLC header, followed by a NLPID and the PPP payload.

## 8. Detection And Recovery From Unsolicited PPP Encapsulation Transitions

When the virtual connection loses state, the PPP encapsulation technique may uni-laterally and unexpectedly change across such transitions. Detection and recovery procedures are defined for the following state transitions:

VC-multiplexed PPP changing to LLC encapsulated PPP

LLC encapsulated PPP changing to VC-multiplexed PPP

When LLC-encapsulated PPP is being used, the initial 6 octets of the LCP packets contain the sequence: fe-fe-03-cf-c0-21. This sequence constitutes the first 6 octets of the FUNI frame. In the case of VC-multiplexed PPP, initial LCP packets contain the sequence c0-21.

In the case of FUNI, this sequence follows the FUNI Header. When a LCP Configure-Request packet is received and recognized, the PPP link enters Link Establishment phase.

Once PPP has entered the Network-layer Protocol phase, and successfully negotiated a particular NCP for a PPP Protocol, if a frame arrives using an alternate but equivalent data encapsulation as defined in [4], then the PPP Link **MUST**:

For a SVC, immediately clear the call with the cause value 111, "protocol error, unspecified".

For a PVC: tear down the active NCPs, **SHOULD** generate an error message, enter the Termination state, and silently drop all received packets.

These policies prevent "black-holes" that occur when the peer loses state. An implementation which requires PPP link configuration, and other PPP negotiated features (such as authentication), **MAY** enter Termination state when configuration fails.

## 9. LCP Configuration Options

The Magic Number LCP configuration option is **RECOMMENDED**, and the Protocol Field Compression (PFC) option is **NOT RECOMMENDED**. An implementation **MUST NOT** request any of the following options, and **MUST** reject a request for such an option:

Field Check Sequence (FCS) Alternatives,

Address-and-Control-Field-Compression (ACFC),

Asynchronous-Control-Character-Map (ACCM)

The Maximum-Receive-Unit (MRU) option **MUST NOT** be negotiated to a larger size than the maximum CPCS-SDU size specified in the associated direction for the virtual connection's traffic contract.

When viewed peer to peer, a PPP link may be bridged over multiple physical layer sections. For each such FUNI section, the LCP framing options **MUST** be actively negotiated by the bridging convertors independently of the LCP framing options in use by other physical layer sections.

**Implementation Note:**

When an ATM FUNI PVC is in the "Stopped" state, it is RECOMMENDED that the implementation wait for Configure-Requests. See the implementation option in reference [1] section 4.2, the "Stopped State" sub-section.

**10. Security Considerations**

Generally, ATM networks are virtual circuit based, and security is implicit in the public data networking service provider's administration of Permanent Virtual Circuits (PVCs) between the network boundaries. The probability of a security breach caused by mis-routed ATM cells is considered to be negligible.

When a public ATM network supports Switched Virtual Circuits, the protocol model becomes analogous to traditional voice band modem dial up over the Public Telephone Switched Network (PTSN). The same PAP/CHAP authentication protocols that are already widely in use for Internet dial up access are leveraged. As a consequence, PPP over FUNI security is at parity with those practices already established by the existing Internet infrastructure.

Those applications that require stronger security are encouraged to use authentication headers, or encrypted payloads, and/or ATM-layer security services.

When using LLC-encapsulated PPP over a virtual connection, an end point can not assume that the PPP session authentication and related security mechanisms also secure the other LLC encapsulated flows on that same virtual connection.

**11. Acknowledgments**

This design is based on work performed in ADSL Forum's Packet Mode Working Group. It is inspired by "PPP in Frame Relay", RFC 1973, by William Simpson. Special thanks to Phil Rakity of Flowpoint, Tim Kwok of Microsoft, and David Allan of Nortel for their constructive review and commentary.
