Multiprotocol Label Switching (MPLS) Label Switching Router (LSR) Management Information Base (MIB)

Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

1. Introduction

This memo defines an portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes managed objects for modeling a Multiprotocol Label Switching (MPLS) [RFC3031] Label Switching Router (LSR).

Comments should be made directly to the MPLS mailing list at mpls@uu.net.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14, RFC 2119, reference [RFC2119].

2. Terminology

This document uses terminology from the document describing the MPLS architecture [RFC3031]. A label switched path (LSP) is modeled as a connection consisting of one or more incoming segments (in-segments) and/or one or more outgoing segments (out-segments) at a LSR. The association or interconnection of the in-segments and out-segments is accomplished by using a cross-connect. We use the terminology "connection" and "LSP" interchangeably where the meaning is clear from the context.

in-segment	This is analogous to an MPLS label.
out-segment	This is analogous to an MPLS label.
cross-connect	This describes the conceptual connection between a set of in-segments and out-segments. Note that either set may be 0; that is, a cross-connect may connect only out-segments together with no in-segments in the case where an LSP is originating on an LSR.

3. The SNMP Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [RFC3410].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIV2, which is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].

4. Outline

Configuring LSPs through an LSR involves the following steps:

- Enabling MPLS on MPLS capable interfaces.
- Configuring in-segments and out-segments.
- Setting up the cross-connect table to associate segments and/or to indicate connection origination and termination.
- Optionally specifying label stack actions.

- Optionally specifying segment traffic parameters.

4.1. Summary of LSR MIB Module

The MIB objects for performing these actions consist of the following tables:

- The interface table (mplsInterfaceTable), which is used for revealing the MPLS protocol on MPLS-capable interfaces.
- The in-segment (mplsInSegmentTable) and out-segment (mplsOutSegmentTable) tables, which are used for configuring LSP segments at an LSR.
- The cross-connect table (mplsXCTable), which is used to associate in and out segments together, in order to form a cross-connect.
- The label stack table (mplsLabelStackTable), which is used for specifying label stack operations.

Further, the MPLS in-segment and out-segment performance tables, mplsInSegmentPerfTable and mplsOutSegmentPerfTable, contain the objects necessary to measure the performance of LSPs, and mplsInterfacePerfTable has objects to measure MPLS performance on a per-interface basis.

These tables are described in the subsequent sections.

5. Brief Description of MIB Module Objects

Sections 5.1-5.2 describe objects pertaining to MPLS-capable interfaces of an LSR. The objects described in Sections 5.3-5.8, were derived from the Incoming Label Map (ILM) and Next Hop Label Forwarding Entry (NHLFE) as specified in the MPLS architecture document [RFC3031]. It is appropriate to note that the in-segment, out-segment, and cross-connect tables were modeled after similar tables found in [RFC2515].

5.1. mplsInterfaceTable

This table represents the interfaces that are MPLS capable. An LSR creates an entry in this table for every MPLS capable interface on that LSR.

5.2. mplsInterfacePerfTable

This table contains objects to measure the MPLS performance of MPLS capable interfaces and is an AUGMENT to mplsInterfaceTable.

5.3. mplsInSegmentTable

This table contains a description of the incoming MPLS segments to an LSR and their associated parameters. This index for this table is mplsInSegmentIndex. The index structure of this table is specifically designed to handle many different MPLS implementations that manage their labels both in a distributed and centralized manner.

The table is designed to handle existing MPLS labels as well as future label strategies that may require labels longer than the ones defined in RFC3031. In these cases, the object mplsInSegmentLabelPtr may be used indicate the first accessible object in a separate table that can be used to represent the label because it is too long to be represented in a single 32-bit value (mplsInSegmentLabel).

5.4. mplsInSegmentPerfTable

The MPLS in-Segment Performance Table has objects to measure the performance of an incoming segment configured on an LSR. It is an AUGMENT to mplsInSegmentTable. High capacity counters are provided for objects that are likely to wrap around quickly on high-speed interfaces.

5.5. mplsOutSegmentTable

The out-Segment Table contains a description of the outgoing MPLS segments at an LSR and their associated parameters.

5.6. mplsOutSegmentPerfTable

The MPLS out-Segment Table contains objects to measure the performance of an outgoing segment configured on an LSR. It is an AUGMENT to mplsOutSegmentTable. High capacity counters are provided for objects that are likely to wrap around quickly on high-speed interfaces.

5.7. mplsXCTable

The mplsXCTable specifies information for associating segments together in order to instruct the LSR to switch between the specified segments. It supports point-to-point, point-to-multipoint and multipoint-to-point connections.

The operational status object indicates the packet forwarding state of a cross-connect entry. For example, when the operational status object is 'down' it indicates that the specified cross-connect entry will not forward packets. Likewise, when it is set to 'up' it indicates that packets will be forwarded.

The administrative status object indicates the forwarding state desired by the operator.

5.8. mplsLabelStackTable

The mplsLabelStackTable specifies the label stack to be pushed onto a packet, beneath the top label. Entries to this table are referred to from mplsXCTable.

5.9 mplsInSegmentMapTable

The mplsInSegmentMapTable specifies the mapping from the mplsInSegmentIndex to the corresponding mplsInSegmentInterface and mplsInSegmentLabel objects. The purpose of this table is to provide the manager with an alternative means by which to locate in-segments. For instance, this table can be useful when tracing LSPs from LSR to LSR by first following the in-segment to out-segment, retrieving the outgoing label and out-going interface, and then proceeding to interrogate this table at the next-hop LSR to continue the trace.

6. Use of 32-bit and 64-bit Counters

64-bit counters are provided in this MIB module for high speed interfaces where the use of 32-bit counters might be impractical. The requirements on the use of 32-bit and 64-bit counters (copied verbatim from [RFC2863]) are as follows.

For interfaces that operate at 20,000,000 (20 million) bits per second or less, 32-bit byte and packet counters MUST be supported. For interfaces that operate faster than 20,000,000 bits/second, and slower than 650,000,000 bits/second, 32-bit packet counters MUST be supported and 64-bit octet counters MUST be supported. For interfaces that operate at 650,000,000 bits/second or faster, 64-bit packet counters AND 64-bit octet counters MUST be supported.

7. Example of LSP Setup

In this section we provide a brief example of setting up an LSP using this MIB module's objects. While this example is not meant to illustrate every nuance of the MIB module, it is intended as an aid to understanding some of the key concepts. It is meant to be read after going through the MIB module itself.

Suppose that one would like to manually create a best-effort, unidirectional LSP. Assume that the LSP enters the LSR via MPLS interface A with ifIndex 12 and exits the LSR via MPLS interface B with ifIndex 13. Let us assume that we do not wish to impose any additional label stack beneath the top label on the outgoing labeled packets. The following example illustrates which rows and corresponding objects might be created to accomplish this. Those objects relevant to illustrating the relationships amongst different tables are shown here. Other objects may be needed before conceptual row activation can happen.

The RowStatus values shown in this section are those to be used in the set request, typically createAndGo(4) which is used to create the conceptual row and have its status immediately set to active. Note that the proper use of createAndGo(4) requires that all columns that do not have a DEFVAL to be specified in order for the SET to succeed. In the example below we have not specify all such columns for the sake of keeping the example short. Please keep in mind that all such fields must be send during a real SET operation. A subsequent retrieval operation on the conceptual row will return a different value, such as active(1). Please see [RFC2579] for a detailed discussion on the use of RowStatus.

We first create a cross-connect entry that associates the desired segments together.

In mplsXCTable:

```
{
    mplsXCIndex                = 0x02,
    mplsXCInSegmentIndex       = 0x00000015,
    mplsXCOutSegmentIndex      = 0x01,

    mplsXCLspId                = 0x0102 -- unique ID
    mplsXCLabelStackIndex      = 0x00, -- only a single
                                -- outgoing label
    mplsXCRowStatus             = createAndGo(4)
}
```

Next, we create the appropriate in-segment and out-segment entries based on the cross-connect. Note that some agents may wish to automatically create the in and out-segments based on the cross-connect creation.

In mplsInSegmentTable:

```
{
    mplsInSegmentIndex         = 0x00000015
    mplsInSegmentLabel         = 21, -- incoming label
}
```

```

mplsInSegmentNPop          = 1,
mplsInSegmentInterface     = 12, -- incoming interface

-- RowPointer MUST point to the first accessible column.
mplsInSegmentLabelPtr      = 0.0,
mplsInSegmentTrafficParamPtr = 0.0,

mplsInSegmentRowStatus     = createAndGo(4)
}

In mplsOutSegmentTable:
{
    mplsOutSegmentIndex      = 0x01,
    mplsOutSegmentInterface  = 13, -- outgoing interface
    mplsOutSegmentPushTopLabel = true(1),
    mplsOutSegmentTopLabel   = 22, -- outgoing label

    -- RowPointer MUST point to the first accessible column.
    mplsOutSegmentTrafficParamPtr = 0.0,
    mplsOutSegmentLabelPtr      = 0.0,

    mplsOutSegmentRowStatus    = createAndGo(4)
}

```

Note that the mplsInSegmentXCIndex and mplsOutSegmentXCIndex objects will automatically be populated with the string 0x02 when these segments are referred to from the corresponding cross-connect entry.

8. Application of the Interface Group to MPLS

RFC2863 defines generic managed objects for managing interfaces. This memo contains the media-specific extensions to the Interfaces Group for managing MPLS interfaces.

This memo assumes the interpretation of the Interfaces Group to be in accordance with [RFC2863] which states that the interfaces table (ifTable) contains information on the managed resource's interfaces and that each sub-layer below the internetwork layer of a network interface is considered an interface. Thus, the MPLS interface is represented as an entry in the ifTable. The inter-relation of entries in the ifTable is defined by Interfaces Stack Group defined in [RFC2863].

When using MPLS interfaces, the interface stack table might appear as follows:

```

+-----+
| MPLS interface; ifType = mpls(166)  +
+-----+
|           Underlying Layer          +
+-----+

```

In the above diagram, "Underlying Layer" refers to the ifIndex of any interface type for which MPLS interworking has been defined. Examples include ATM, Frame Relay, Ethernet, etc.

8.1. Support of the MPLS Layer by ifTable

Some specific interpretations of ifTable for the MPLS layer follow.

Object	Use for the MPLS layer
ifIndex	Each MPLS interface is represented by an ifEntry.
ifDescr	Description of the MPLS interface.
ifType	The value that is allocated for MPLS is 166.
ifSpeed	The total bandwidth in bits per second for use by the MPLS layer.
ifPhysAddress	Unused.
ifAdminStatus	This variable indicates the administrator's intent as to whether MPLS should be enabled, disabled, or running in some diagnostic testing mode on this interface. Also see [RFC2863].
ifOperStatus	This value reflects the actual operational status of MPLS on this interface.
ifLastChange	See [RFC2863].
ifInOctets	The number of received octets over the interface, i.e., the number of received, octets received as labeled packets.
ifOutOctets	The number of transmitted octets over the interface, i.e., the number of octets transmitted as labeled packets.

ifInErrors The number of labeled packets dropped due to uncorrectable errors.

ifInUnknownProtos
The number of received packets discarded during packet header validation, including packets with unrecognized label values.

ifOutErrors See [RFC2863].

ifName Textual name (unique on this system) of the interface or an octet string of zero length.

ifLinkUpDownTrapEnable
Default is disabled (2).

ifConnectorPresent
Set to false (2).

ifHighSpeed See [RFC2863].

ifHCInOctets The 64-bit version of ifInOctets; supported if required by the compliance statements in [RFC2863].

ifHCOctets The 64-bit version of ifOutOctets; supported if required by the compliance statements in [RFC2863].

ifAlias The non-volatile 'alias' name for the interface as specified by a network manager.

ifCounterDiscontinuityTime
See [RFC2863].

9. The Use of RowPointer

RowPointer is a textual convention used to identify a conceptual row in a MIB Table by pointing to the first accessible object in that row. In this MIB module, the trafficParamPtr object from either the mplsInSegmentTable or mplsOutSegmentTable SHOULD indicate the first accessible column in an entry in the MplsTunnelResourceEntry in the MPLS-TE-STD-MIB [RFC3812] to indicate the traffic parameter settings for this segment, if it represents an LSP used for a TE tunnel.

The trafficParamPtr object may optionally point at an externally defined traffic parameter specification table. A value of zeroDotZero indicates best-effort treatment. By having the same value of this object, two or more segments can indicate resource sharing of such things as LSP queue space, etc.

DESCRIPTION

"This MIB module contains managed object definitions for
the Multiprotocol Label Switching (MPLS) Router as

defined in: Rosen, E., Viswanathan, A., and R. Callon, Multiprotocol Label Switching Architecture, RFC 3031, January 2001.

Copyright (C) The Internet Society (2004). The initial version of this MIB module was published in RFC 3812. For full legal notices see the RFC itself or see:
<http://www.ietf.org/copyrights/ianamib.html>

-- Revision history.

REVISION

"200406030000Z" -- June 3, 2004

DESCRIPTION

"Initial revision, published as part of RFC 3813."

::= { mplsStdMIB 2 }

-- TEXTUAL-CONVENTIONS

MplsIndexType ::= TEXTUAL-CONVENTION

STATUS current

DESCRIPTION

"This is an octet string that can be used as a table index in cases where a large addressable space is required such as on an LSR where many applications may be provisioning labels.

Note that the string containing the single octet with the value 0x00 is a reserved value used to represent special cases. When this TEXTUAL-CONVENTION is used as the SYNTAX of an object, the DESCRIPTION clause MUST specify if this special value is valid and if so what the special meaning is.

In systems that provide write access to the MPLS-LSR-STD MIB, mplsIndexType SHOULD be used as a simple multi-digit integer encoded as an octet string. No further overloading of the meaning of an index SHOULD be made.

In systems that do not offer write access to the MPLS-LSR-STD MIB, the mplsIndexType may contain implicit formatting that is specific to the implementation to convey additional information such as interface index, physical card or device, or application id. The interpretation of this additional formatting is implementation dependent and not covered in this document. Such formatting MUST

NOT impact the basic functionality of read-only access to the MPLS-LSR-STD MIB by management applications that are not aware of the formatting rules."

SYNTAX OCTET STRING (SIZE(1..24))

MplsIndexNextType ::= TEXTUAL-CONVENTION

STATUS current

DESCRIPTION

"When a MIB module is used for configuration, an object with this SYNTAX always contains a legal value (a non-zero-length string) for an index that is not currently used in the relevant table. The Command Generator (Network Management Application) reads this variable and uses the (non-zero-length string) value read when creating a new row with an SNMP SET.

When the SET is performed, the Command Responder (agent) must determine whether the value is indeed still unused; Two Network Management Applications may attempt to create a row (configuration entry) simultaneously and use the same value. If it is currently unused, the SET succeeds and the Command Responder (agent) changes the value of this object, according to an implementation-specific algorithm. If the value is in use, however, the SET fails. The Network Management Application must then re-read this variable to obtain a new usable value.

Note that the string containing the single octet with the value 0x00 is a reserved value used to represent the special case where no additional indexes can be provisioned, or in systems that do not offer write access, objects defined using this TEXTUAL-CONVENTION MUST return the string containing the single octet with the value 0x00."

mplsInterfaceTable OBJECT-TYPE

SYNTAX SEQUENCE OF MplsInterfaceEntry
 MAX-ACCESS not-accessible
 STATUS current
 DESCRIPTION
 "This table specifies per-interface MPLS capability
 and associated information."
 ::= { mplsLsrObjects 1 }

mplsInterfaceEntry OBJECT-TYPE
 SYNTAX MplsInterfaceEntry
 MAX-ACCESS not-accessible
 STATUS current
 DESCRIPTION
 "A conceptual row in this table is created
 automatically by an LSR for every interface capable
 of supporting MPLS and which is configured to do so.
 A conceptual row in this table will exist if and only if
 a corresponding entry in ifTable exists with ifType =
 mpls(166). If this associated entry in ifTable is
 operationally disabled (thus removing MPLS
 capabilities on that interface), the corresponding
 entry in this table MUST be deleted shortly thereafter.
 An conceptual row with index 0 is created if the LSR
 supports per-platform labels. This conceptual row
 represents the per-platform label space and contains
 parameters that apply to all interfaces that participate
 in the per-platform label space. Other conceptual rows
 in this table represent MPLS interfaces that may
 participate in either the per-platform or per-
 interface label spaces, or both. Implementations
 that either only support per-platform labels,
 or have only them configured, may choose to return
 just the mplsInterfaceEntry of 0 and not return
 the other rows. This will greatly reduce the number
 of objects returned. Further information about label
 space participation of an interface is provided in
 the DESCRIPTION clause of
 mplsInterfaceLabelParticipationType."

STATUS current
DESCRIPTION
 "This value indicates the total amount of available
 bandwidth available on this interface and is
 specified in kilobits per second (Kbps). This value
 is calculated as the difference between the amount
 of bandwidth currently in use and that specified in
 mplsInterfaceTotalBandwidth. This variable is not
 applicable when applied to the interface with index
 0. When this value cannot be measured, this value
 should contain the nominal bandwidth."
 ::= { mplsInterfaceEntry 7 }

mplsInterfaceLabelParticipationType OBJECT-TYPE

SYNTAX BITS {
 perPlatform (0),
 perInterface (1)
 }
MAX-ACCESS read-only

STATUS current

DESCRIPTION

"If the value of the `mplsInterfaceIndex` for this entry is zero, then this entry corresponds to the per-platform label space for all interfaces configured to use that label space. In this case the `perPlatform(0)` bit MUST be set; the `perInterface(1)` bit is meaningless and MUST be ignored.

The remainder of this description applies to entries with a non-zero value of `mplsInterfaceIndex`.

If the `perInterface(1)` bit is set then the value of `mplsInterfaceLabelMinIn`, `mplsInterfaceLabelMaxIn`, `mplsInterfaceLabelMinOut`, and `mplsInterfaceLabelMaxOut` for this entry reflect the label ranges for this interface.

If only the `perPlatform(0)` bit is set, then the value of `mplsInterfaceLabelMinIn`, `mplsInterfaceLabelMaxIn`, `mplsInterfaceLabelMinOut`, and `mplsInterfaceLabelMaxOut` for this entry MUST be identical to the instance of these objects with index 0. These objects may only vary from the entry with index 0 if both the `perPlatform(0)` and `perInterface(1)` bits are set.

In all cases, at a minimum one of the `perPlatform(0)` or `perInterface(1)` bits MUST be set to indicate that at least one label space is in use by this interface. In all cases, agents MUST ensure that label ranges are specified consistently and MUST return an `inconsistentValue` error when they do not."

STATUS current

DESCRIPTION

"This object contains the next available value to be used for mplsInSegmentIndex when creating entries in the mplsInSegmentTable. The special value of a string containing the single octet 0x00 indicates that no new entries can be created in this table. Agents not allowing managers to create entries

in this table MUST set this object to this special value."
 ::= { mplsLsrObjects 3 }

-- in-segment table.

mplsInSegmentTable OBJECT-TYPE
SYNTAX SEQUENCE OF MplsInSegmentEntry
MAX-ACCESS not-accessible
STATUS current
DESCRIPTION
"This table contains a description of the incoming MPLS segments (labels) to an LSR and their associated parameters. The index for this table is mplsInSegmentIndex. The index structure of this table is specifically designed to handle many different MPLS implementations that manage their labels both in a distributed and centralized manner. The table is also designed to handle existing MPLS labels as defined in RFC3031 as well as longer ones that may be necessary in the future.

In cases where the label cannot fit into the mplsInSegmentLabel object, the mplsInSegmentLabelPtr will indicate this by being set to the first accessible column in the appropriate extension table's row. In this case an additional table MUST be provided and MUST be indexed by at least the indexes used by this table. In all other cases when the label is represented within the mplsInSegmentLabel object, the mplsInSegmentLabelPtr MUST be set to 0.0. Due to the fact that MPLS labels may not exceed 24 bits, the mplsInSegmentLabelPtr object is only a provision for future-proofing the MIB module. Thus, the definition of any extension tables is beyond the scope of this MIB module."

::= { mplsLsrObjects 4 }

mplsInSegmentEntry OBJECT-TYPE
SYNTAX MplsInSegmentEntry
MAX-ACCESS not-accessible
STATUS current
DESCRIPTION
"An entry in this table represents one incoming segment as is represented in an LSR's LFIB. An entry can be created by a network administrator or an SNMP agent, or an MPLS signaling protocol. The creator of the entry is denoted by mplsInSegmentOwner.

The value of `mplsInSegmentRowStatus` cannot be `active(1)` unless the `ifTable` entry corresponding to `mplsInSegmentInterface` exists. An entry in this table must match any incoming packets, and indicates an instance of `mplsXCEnt` based on which forwarding and/or switching actions are taken."

```
INDEX { mplsInSegmentIndex }
      ::= { mplsInSegmentTable 1 }

```
mplsInSegmentInterface OBJECT-TYPE
    SYNTAX      InterfaceIndexOrZero
    MAX-ACCESS   read-create
    STATUS       current
    DESCRIPTION
        "This object represents the
         interface index for the incoming MPLS interface. A
         value of zero represents all interfaces participating in
         the per-platform label space. This may only be used
         in cases where the incoming interface and label
         are associated with the same mplsXCEnt. Specifically,
         given a label and any incoming interface pair from the
         per-platform label space, the outgoing label/interface
         mapping remains the same. If this is not the case,
         then individual entries MUST exist that
```

can then be mapped to unique mplsXCEntries."

mplsOutSegmentEntry OBJECT-TYPE**SYNTAX** MplsOutSegmentEntry**MAX-ACCESS** not-accessible**STATUS** current**DESCRIPTION**

"An entry in this table represents one outgoing

segment. An entry can be created by a network administrator, an SNMP agent, or an MPLS signaling protocol. The object `mplsOutSegmentOwner` indicates the creator of this entry. The value of `mplsOutSegmentRowStatus` cannot be `active(1)` unless the `ifTable` entry corresponding to `mplsOutSegmentInterface` exists.

Note that the indexing of this table uses a single, arbitrary index (`mplsOutSegmentIndex`) to indicate which out-segment (i.e.: label) is being switched to from which in-segment (i.e.: label) or in-segments. This is necessary because it is possible to have an equal-cost multi-path situation where two identical out-going labels are assigned to the same cross-connect (i.e.: they go to two different neighboring LSRs); thus, requiring two out-segments. In order to preserve the uniqueness of the references by the `mplsXCEntry`, an arbitrary integer must be used as the index for this table."

DESCRIPTION

"This table specifies information for switching between LSP segments. It supports point-to-point, point-to-multipoint and multipoint-to-point connections. mplsLabelStackTable specifies the label stack information for a cross-connect LSR and is referred to from mplsXCTable."

::= { mplsLsrObjects 10 }

mplsXCEntry OBJECT-TYPE

SYNTAX MplsXCEntry

MAX-ACCESS not-accessible

STATUS current

DESCRIPTION

"A row in this table represents one cross-connect entry. It is indexed by the following objects:

- cross-connect index mplsXCIndex that uniquely identifies a group of cross-connect entries
- in-segment index, mplsXCInSegmentIndex
- out-segment index, mplsXCOutSegmentIndex

LSPs originating at this LSR:

These are represented by using the special value of `mplsXCInSegmentIndex` set to the string containing a single octet 0x00. In this case the `mplsXCOutSegmentIndex` MUST not be the string containing a single octet 0x00.

LSPs terminating at this LSR:

These are represented by using the special value `mplsXCOutSegmentIndex` set to the string containing a single octet 0x00.

Special labels:

Entries indexed by the strings containing the reserved MPLS label values as a single octet 0x00 through 0x0f (inclusive) imply LSPs terminating at this LSR. Note that situations where LSPs are terminated with incoming label equal to the string containing a single octet 0x00 can be distinguished from LSPs originating at this LSR because the `mplsXCOutSegmentIndex` equals the string containing the single octet 0x00.

An entry can be created by a network administrator or by an SNMP agent as instructed by an MPLS signaling protocol."

11. Security Considerations

It is clear that this MIB module is potentially useful for monitoring of MPLS LSRs. This MIB can also be used for configuration of certain objects, and anything that can be configured can be incorrectly configured, with potentially disastrous results.

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations. These are the tables and objects and their sensitivity/vulnerability:

- o the `mplsLsrInSegmentTable`, `mplsLsrOutSegmentTable`, `mplsXCTable`, `mplsOutSegmentPerfTable`, `mplsInterfacePerfTable`, and `mplsInSegmentPerfTable` collectively contain objects to provision MPLS interfaces, LSPs and their associated parameters on an Label Switching Router (LSR). Unauthorized access to objects in these tables, could result in disruption of traffic on the network. This is especially true if an LSP has been established. The use of stronger mechanisms such as SNMPv3 security should be considered where possible. Specifically, SNMPv3 VACM and USM MUST be used with any v3 agent which implements this MIB module. Administrators should consider whether read access to these objects should be allowed, since read access may be undesirable under certain circumstances.

Some of the readable objects in this MIB module "i.e., objects with a MAX-ACCESS other than not-accessible" may be considered sensitive or vulnerable in some network environments. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP. These are the tables and objects and their sensitivity/vulnerability:

- o the `mplsLsrInSegmentTable`, `mplsLsrOutSegmentTable`, `mplsXCTable`, `mplsOutSegmentPerfTable`, `mplsInterfacePerfTable`, and `mplsInSegmentPerfTable` collectively show the LSP network topology and its performance characteristics. If an Administrator does not want to reveal this information, then these tables should be considered sensitive/vulnerable.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure "for example by using IPSec", even then, there is no control as to who on the secure network is allowed to access and GET/SET "read/change/create/delete" the objects in this MIB module.

It is RECOMMENDED that implementers consider the security features as provided by the SNMPv3 framework "see [RFC3410], section 8", including full support for the SNMPv3 cryptographic mechanisms "for authentication and privacy".

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of this MIB module, is properly configured to give access to the objects only to those principals "users" that have legitimate rights to indeed GET or SET "change/create/delete" them.

12. Acknowledgments

We wish to thank Ron Bonica, Adrian Farrel, Eric Gray, Tim Mancour, Keith McCloghrie, Bala Rajagopalan, Dan Tappan, Vasanthi Thirumalai, Joseph Benoit, Mike Piecuch, Joan Cucchiara. A special thanks to Bert Wijnen and Mike MacFaden for really getting the MIB module into shape.

13. IANA Considerations

As described in [MPLSMGMT] and as requested in the MPLS-TC-STD-MIB [RFC3811], MPLS related standards track MIB modules should be rooted under the mplsStdMIB subtree. There are 4 MPLS MIB Modules contained in this document, each of the following "IANA Considerations" subsections requests IANA for a new assignment under the mplsStdMIB subtree. New assignments can only be made via a Standards Action as specified in [RFC2434].

13.1. IANA Considerations for MPLS-LSR-STD-MIB

The IANA has assigned { mplsStdMIB 2 } to the MPLS-LSR-STD-MIB module specified in this document.
