## Distributed Denial-of-Service Open Threat Signaling (DOTS) Telemetry

### Abstract

This document aims to enrich the Distributed Denial-of-Service Open Threat Signaling (DOTS) signal channel protocol with various telemetry attributes, allowing for optimal Distributed Denial-of-Service (DDoS) attack mitigation. It specifies the normal traffic baseline and attack traffic telemetry attributes a DOTS client can convey to its DOTS server in the mitigation request, the mitigation status telemetry attributes a DOTS server can communicate to a DOTS client, and the mitigation efficacy telemetry attributes a DOTS client can communicate to a DOTS server. The telemetry attributes can assist the mitigator in choosing the DDoS mitigation techniques and performing optimal DDoS attack mitigation.

This document specifies two YANG modules: one for representing DOTS telemetry message types and one for sharing the attack mapping details over the DOTS data channel.

### Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 7841.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at <https://www.rfc-editor.org/info/rfc9244>.

## 1. Introduction

IT organizations and service providers are facing Distributed Denial-of-Service (DDoS) attacks that fall into two broad categories:

1. Network-layer and transport-layer attacks target the victim's infrastructure. These attacks are not necessarily aimed at taking down the actual delivered services; rather, these attacks prevent various network elements (routers, switches, firewalls, transit links, and so on) from serving legitimate users' traffic.

The main method of such attacks is to send a large volume of traffic (e.g., high-pps (packets per second) traffic) toward the victim's infrastructure. Typically, attack volumes may vary from a few hundred Mbps to hundreds of Gbps or even Tbps. Attacks are commonly carried out leveraging botnets and attack reflectors for amplification attacks (Section 3.1 of [RFC4732]) such as NTP (Network Time Protocol), DNS (Domain Name System), SNMP (Simple Network Management Protocol), or SSDP (Simple Service Discovery Protocol).

2. Application-layer attacks target various applications. Typical examples include attacks against HTTP/HTTPS, DNS, SIP (Session Initiation Protocol), or SMTP (Simple Mail Transfer Protocol). However, all applications with their port numbers open at network edges can be attractive attack targets.

Application-layer attacks are considered more complex and harder to categorize and are therefore harder to detect and mitigate efficiently.

To compound the problem, attackers also leverage multi-vectorized attacks. These attacks are assembled from dynamic network-layer and application-layer attack vectors and other tactics. As such, multiple attack vectors formed by multiple attack types and volumes

are launched simultaneously toward a victim. Multi-vector attacks are harder to detect and defend against. Multiple and simultaneous mitigation techniques are needed to defeat such attack campaigns. It is also common for attackers to change attack vectors right after a successful mitigation, burdening their opponents with changing their defense methods.

The conclusion derived from the aforementioned attack scenarios is that modern attack detection and mitigation are most certainly complicated and highly convoluted tasks. They demand a comprehensive knowledge of the attack attributes and the normal behavior of the targeted systems (including normal traffic patterns), as well as the attacker's ongoing and past actions. Even more challenging, retrieving all the analytics needed for detecting these attacks is not simple with the industry's current reporting capabilities.

The Distributed Denial-of-Service Open Threat Signaling (DOTS) signal channel protocol [RFC9132] is used to carry information about a network resource or a network (or a part thereof) that is under a DDoS attack. Such information is sent by a DOTS client to one or multiple DOTS servers so that appropriate mitigation actions are undertaken on traffic deemed suspicious. Various use cases are discussed in [RFC8903].

DOTS clients can be integrated within a DDoS attack detector or within network and security elements that have been actively engaged with ongoing attacks. The DOTS client mitigation environment determines that it is no longer possible or practical for it to handle these attacks itself. This can be due to a lack of resources or security capabilities, as derived from the complexities and intensity of these attacks. In this circumstance, the DOTS client has invaluable knowledge about the actual attacks that need to be handled by its DOTS server(s). By enabling the DOTS client to share this comprehensive knowledge of an ongoing attack under specific circumstances, the DOTS server can drastically increase its ability to accomplish successful mitigation. While the attack is being handled by the mitigation resources associated with the DOTS server, the DOTS server has knowledge about the ongoing attack mitigation. The DOTS server can share this information with the DOTS client so that the client can better assess and evaluate the actual mitigation realized.

DOTS clients can send mitigation hints derived from attack details to DOTS servers, with the full understanding that a DOTS server may ignore mitigation hints, as described in [RFC8612] (Gen-004). Mitigation hints will be transmitted across the DOTS signal channel, as the data channel may not be functional during an attack. How a DOTS server handles normal and attack traffic attributes, and mitigation hints, is implementation specific.

Both DOTS clients and servers can benefit from this information by presenting various information details in relevant management, reporting, and portal systems.

This document defines DOTS telemetry attributes that can be conveyed by DOTS clients to DOTS servers, and vice versa. The DOTS telemetry

attributes are not mandatory attributes of the DOTS signal channel protocol [RFC9132]. When no limitation policy is provided to a DOTS agent, it can signal available telemetry attributes to its peers in order to optimize the overall mitigation service provisioned using DOTS. The aforementioned policy can be, for example, agreed upon during a service subscription (which is out of scope for this document) to identify a subset of DOTS clients among those deployed in a DOTS client domain that are allowed to send or receive telemetry data.

Section 11.2 of this document specifies a YANG module that augments the DOTS data channel [RFC8783] with information related to attack details. Sharing such details during 'idle' time is meant to optimize the data exchanged over the DOTS signal channel.

## 2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

The reader should be familiar with the terms defined in [RFC8612].

"DOTS telemetry" is defined as the collection of attributes that are used to characterize the normal traffic baseline, attacks and their mitigation measures, and any related information that may help in enforcing countermeasures. "DOTS telemetry" is an optional set of attributes that can be signaled in the DOTS signal channel protocol.

The Telemetry Setup Identifier (tsid) is an identifier that is generated by DOTS clients to uniquely identify DOTS telemetry setup configuration data. See Section 7.1.2 for more details.

The Telemetry Identifier (tmid) is an identifier that is generated by DOTS clients to uniquely identify DOTS telemetry data that is communicated prior to or during a mitigation. See Section 8.2 for more details.

"Overlapped" lower numeric 'tsid' (or 'tmid') refers to the lower 'tsid' (or 'tmid') value of two overlapping telemetry requests.

The term "pipe" represents the maximum level of traffic that the DOTS client domain can receive. Whether a "pipe" is mapped to one or a group of network interfaces is deployment specific. For example, each interconnection link may be considered as a specific pipe if the DOTS server is hosted by each upstream provider, while the aggregate of all links to connect to upstream network providers can be considered by a DOTS client domain as a single pipe when communicating with a DOTS server not hosted by these upstream providers.

This document uses IANA-assigned Enterprise Numbers. These numbers are also known as "Private Enterprise Numbers" and "SMI (Structure of Management Information) Network Management Private Enterprise Codes"

[Private-Enterprise-Numbers].

The meanings of the symbols in YANG tree diagrams are defined in [RFC8340] and [RFC8791].

Consistent with the convention set in Section 2 of [RFC8783], the examples in Section 8.1.6 use "/restconf" as the discovered RESTCONF API root path. Within these examples, some protocol header lines are split into multiple lines for display purposes only. When a line ends with a backslash ("\") as the last character, the line is wrapped for display purposes. It is considered to be joined to the next line by deleting the backslash, the following line break, and the leading whitespace of the next line.

### 3. DOTS Telemetry: Overview and Purpose

Timely and effective signaling of up-to-date DDoS telemetry to all elements involved in the mitigation process is essential and improves the overall DDoS mitigation service's effectiveness. Bidirectional feedback between DOTS agents is required for increased awareness by each party of the attack and mitigation efforts, supporting a superior and highly efficient attack mitigation service.

#### 3.1. Need for More Visibility

When signaling a mitigation request, it is most certainly beneficial for DOTS clients to signal to DOTS servers any knowledge regarding ongoing attacks. This can happen in cases where DOTS clients are asking DOTS servers for support in defending against attacks that they have already detected and/or (partially) mitigated.

If attacks are already detected and categorized within a DOTS client domain, the DOTS server, and its associated mitigation services, can proactively benefit from this information and optimize the overall service delivery. It is important to note that DOTS client domains' and DOTS server domains' detection and mitigation approaches can be different and can potentially result in different results and attack classifications. The DDoS mitigation service treats the ongoing attack details received from DOTS clients as hints and cannot completely rely on or trust the attack details conveyed by DOTS clients.

In addition to the DOTS server directly using telemetry data as operational hints, the DOTS server's security operation team also benefits from telemetry data. A basic requirement of security operation teams is to be aware of and get visibility into the attacks they need to handle. This holds especially for the case of ongoing attacks, where DOTS telemetry provides data about the current attack status. Even if some mitigation can be automated, operational teams can use the DOTS telemetry information to be prepared for attack mitigation and to assign the correct resources (e.g., operation staff, networking resources, mitigation resources) for the specific service. Similarly, security operations personnel at the DOTS client side ask for feedback about their requests for protection. Therefore, it is valuable for DOTS servers to share DOTS telemetry with DOTS clients.

Mutual sharing of information is thus crucial for "closing the mitigation loop" between DOTS clients and servers. For the server-side team, it is important to confirm that the same attacks that the DOTS server's mitigation resources are seeing are those for which a DOTS client is requesting mitigation. For the DOTS client-side team, it is important to realize that the DOTS clients receive the required service -- for example, understanding that "I asked for mitigation of two attacks, and my DOTS server detects and mitigates only one of them." Cases of inconsistency in attack classification between DOTS clients and servers can be highlighted, and maybe handled, using the DOTS telemetry attributes.

In addition, management and orchestration systems, at both the DOTS client and server sides, can use DOTS telemetry as feedback to automate various control and management activities derived from signaled telemetry information.

If the DOTS server's mitigation resources have the capabilities to facilitate the DOTS telemetry, the DOTS server adapts its protection strategy and activates the required countermeasures immediately (automation enabled) for the sake of optimized attack mitigation decisions and actions. Discussion regarding the interface from the DOTS server to the mitigator to signal the telemetry data is out of scope for this document.

### 3.2. Enhanced Detection

DOTS telemetry can also be used as input for determining what values to use for the tuning parameters available on the mitigation resources. During the last few years, DDoS attack detection technologies have evolved from threshold-based detection (that is, cases when all or specific parts of traffic cross a predefined threshold for a certain period of time is considered as an attack) to an "anomaly detection" approach. For the latter, it is required to maintain rigorous learning of "normal" behavior, and an "anomaly" (or an attack) is identified and categorized based on the knowledge about the normal behavior and a deviation from this normal behavior. Statistical and artificial intelligence algorithms (e.g., machine learning) are used such that the actual traffic thresholds are automatically calculated by learning the protected entity's normal traffic behavior during 'idle' time (i.e., no mitigation is active). The normal traffic characterization learned is referred to as the "normal traffic baseline". An attack is detected when the victim's actual traffic is deviating from this normal baseline pattern.

In addition, subsequent activities toward mitigating an attack are much more challenging. The ability to distinguish legitimate traffic from attacker traffic on a per-packet basis is complex. For example, a packet may look "legitimate" and no attack signature can be identified. The anomaly can be identified only after detailed statistical analysis. DDoS attack mitigators use the normal baseline during the mitigation of an attack to identify and categorize the expected appearance of a specific traffic pattern. Particularly, the mitigators use the normal baseline to recognize the "level of normality" that needs to be achieved during the various mitigation

processes.

Normal baseline calculation is performed based on continuous learning of the normal behavior of the protected entities. The minimum learning period varies from hours to days and even weeks, depending on the protected applications' behavior. The baseline cannot be learned during active attacks because attack conditions do not characterize the protected entities' normal behavior.

If the DOTS client has calculated the normal baseline of its protected entities, signaling such information to the DOTS server along with the attack traffic levels provides value. The DOTS server benefits from this telemetry by tuning its mitigation resources with the DOTS client's normal baseline. The DOTS server's mitigators use the baseline to familiarize themselves with the attack victim's normal behavior and target the baseline as the level of normality they need to achieve. Fed with this information, the overall mitigation performance is expected to be improved in terms of time to mitigate, accuracy, and false-negative and false-positive rates.

Mitigation of attacks without having certain knowledge of normal traffic can be inaccurate at best. This is especially true for recursive signaling (see Section 3.2.3 of [RFC8811]). Given that DOTS clients can be integrated in a highly diverse set of scenarios and use cases, this emphasizes the need for knowledge of the behavior of each DOTS client domain -- especially given that common global thresholds for attack detection can almost never be realized. Each DOTS client domain can have its own levels of traffic and normal behavior. Without facilitating normal baseline signaling, it may be very difficult for DOTS servers in some cases to detect and mitigate the attacks accurately:

- \* It is important to emphasize that it is practically impossible for the DOTS server's mitigators to calculate the normal baseline in cases where they do not have any knowledge of the traffic beforehand.

Of course, this information can be provided using out-of-band mechanisms or manual configuration, at the risk of unmaintained information becoming inaccurate as the network evolves and "normal" patterns change. The use of a dynamic and collaborative means between the DOTS client and server to identify and share key parameters for the sake of efficient DDoS protection is valuable.

### 3.3. Efficient Mitigation

During a high-volume attack, DOTS client pipes can be totally saturated. DOTS clients ask their DOTS servers to handle the attack upstream so that DOTS client pipes return to a reasonable load level (normal pattern, ideally). At this point, it is essential to ensure that the mitigator does not overwhelm the DOTS client pipes by sending back large volumes of "clean traffic", or what it believes is "clean". This can happen when the mitigator has not managed to detect and mitigate all the attacks launched toward the DOTS client domain.

In this case, it can be valuable to DOTS clients to signal to DOTS servers the total pipe capacity, which is the level of traffic the DOTS client domain can absorb from its upstream network. This is usually the circuit size, which includes all the packet overheads. Dynamic updates of the condition of pipes between DOTS agents while they are under a DDoS attack are essential (e.g., where multiple DOTS clients share the same physical connectivity pipes). The DOTS server should activate other mechanisms to ensure that it does not allow the DOTS client domain's pipes to be saturated unintentionally. The rate-limit action defined in [RFC8783] is a reasonable candidate to achieve this objective; the DOTS client can indicate the type(s) of traffic (such as ICMP, UDP, TCP port number 80) it prefers to limit. The rate-limit action can be controlled via the signal channel [RFC9133] even when the pipe is overwhelmed.

## 4. Design Overview

### 4.1. Overview of Telemetry Operations

The DOTS protocol suite is divided into two logical channels: the signal channel [RFC9132] and data channel [RFC8783]. This division is due to the vastly different requirements placed upon the traffic they carry. The DOTS signal channel must remain available and usable even in the face of attack traffic that might, for example, saturate one direction of the links involved, rendering acknowledgment-based mechanisms unreliable and strongly incentivizing messages to be small enough to be contained in a single IP packet (Section 2.2 of [RFC8612]). In contrast, the DOTS data channel is available for high-bandwidth data transfer before or after an attack, using more conventional transport protocol techniques (Section 2.3 of [RFC8612]). It is generally preferable to perform advance configuration over the DOTS data channel, including configuring aliases for static or nearly static data sets such as sets of network addresses/prefixes that might be subject to related attacks. This design helps to optimize the use of the DOTS signal channel for the small messages that are important to deliver during an attack. As a reminder, the DOTS signal channel and data channel both require secure communication channels (Section 11 of [RFC9132] and Section 10 of [RFC8783]).

Telemetry information has aspects that correspond to both operational modes (i.e., signal channel and data channel): there is certainly a need to convey updated information about ongoing attack traffic and targets during an attack, so as to convey detailed information about mitigation status and inform updates to mitigation strategy in the face of adaptive attacks. However, it is also useful to provide mitigation services with a picture of normal or "baseline" traffic toward potential targets to aid in detecting when incoming traffic deviates from normal into being an attack. Also, one might populate a "database" of classifications of known types of attacks so that a short attack identifier can be used during an attack period to describe an observed attack. This specification does make provision for use of the DOTS data channel for the latter function (Section 8.1.6) but otherwise retains most telemetry functionality in the DOTS signal channel.

Note that it is a functional requirement to convey information about ongoing attack traffic during an attack, and information about baseline traffic uses an essentially identical data structure that is naturally defined to sit next to the description of attack traffic. The related telemetry setup information used to parameterize actual traffic data is also sent over the signal channel, out of expediency.

This document specifies an extension to the DOTS signal channel protocol. Considerations about how to establish, maintain, and make use of the DOTS signal channel are specified in [RFC9132].

Once the DOTS signal channel is established, DOTS clients that support the DOTS telemetry extension proceed with the telemetry setup configuration (e.g., measurement interval, telemetry notification interval, pipe capacity, normal traffic baseline) as detailed in Section 7. DOTS agents can then include DOTS telemetry attributes using the DOTS signal channel (Section 8.1). A DOTS client can use separate messages to share with its DOTS server(s) a set of telemetry data bound to an ongoing mitigation (Section 8.2). Also, a DOTS client that is interested in receiving telemetry notifications related to some of its resources follows the procedure defined in Section 8.3. A DOTS client that receives such notifications can then decide to send a mitigation request if an attack cannot be mitigated locally within the DOTS client domain.

Aggregate DOTS telemetry data can also be included in efficacy update (Section 9.1) or mitigation update (Section 9.2) messages.

#### 4.2. Block-Wise Transfers

DOTS clients can use a block-wise transfer [RFC7959] with the recommendation detailed in Section 4.4.2 of [RFC9132] to control the size of a response when the data to be returned does not fit within a single datagram.

DOTS clients can also use the Constrained Application Protocol (CoAP) Block1 Option in a PUT request (Section 2.5 of [RFC7959]) to initiate large transfers, but these Block1 transfers are likely to fail if the inbound "pipe" is running full because the transfer requires a message from the server for each block, which would likely be lost in the incoming flood. Consideration needs to be made to try to fit this PUT into a single transfer or to separate out the PUT into several discrete PUTs where each of them fits into a single packet.

Q-Block1 and Q-Block2 Options that are similar to the CoAP Block1 and Block2 Options, but enable robust transmissions of big blocks of data with less packet interchanges using NON messages, are defined in [RFC9177]. DOTS implementations can consider the use of Q-Block1 and Q-Block2 Options [DOTS-Robust-Blocks].

#### 4.3. DOTS Multihoming Considerations

Considerations for multihomed DOTS clients to select which DOTS server to contact and which IP prefixes to include in a telemetry message to a given peer DOTS server are discussed in [DOTS-Multihoming]. For example, if each upstream network exposes a

DOTS server and the DOTS client maintains DOTS channels with all of them, only the information related to prefixes assigned by an upstream network to the DOTS client domain will be signaled via the DOTS channel established with the DOTS server of that upstream network.

Considerations related to whether (and how) a DOTS client gleans some telemetry information (e.g., attack details) it receives from a first DOTS server and shares it with a second DOTS server are implementation and deployment specific.

#### 4.4. YANG Considerations

Telemetry messages exchanged between DOTS agents are serialized using Concise Binary Object Representation (CBOR) [RFC8949]. CBOR-encoded payloads are used to carry signal-channel-specific payload messages that convey request parameters and response information such as errors.

This document specifies a YANG module [RFC7950] for representing DOTS telemetry message types (Section 11.1). All parameters in the payload of the DOTS signal channel are mapped to CBOR types as specified in Section 12. As a reminder, Section 3 of [RFC9132] defines the rules for mapping YANG-modeled data to CBOR.

The DOTS telemetry module (Section 11.1) is not intended to be used via the Network Configuration Protocol (NETCONF) / RESTCONF for DOTS server management purposes. It serves only to provide a data model and encoding following [RFC8791]. Server deviations (Section 5.6.3 of [RFC7950]) are strongly discouraged, as the peer DOTS agent does not have the means to retrieve the list of deviations and thus interoperability issues are likely to be encountered.

The DOTS telemetry module (Section 11.1) uses "enumerations" rather than "identities" to define units, samples, and intervals because otherwise the namespace identifier "ietf-dots-telemetry" must be included when a telemetry attribute is included (e.g., in a mitigation efficacy update). The use of "identities" is thus suboptimal from the standpoint of message compactness, as message compactness is one of the key requirements for DOTS signal channel messages.

The DOTS telemetry module (Section 11.1) includes some lists for which no "key" statement is included. This behavior is compliant with [RFC8791]. The reason for not including these keys is that they are not included in the message body of DOTS requests; such keys are included as mandatory Uri-Paths in requests (Sections 7 and 8). Otherwise, whenever a "key" statement is used in the module, the same definition as the definition provided in Section 7.8.2 of [RFC7950] is assumed.

Some parameters (e.g., low-percentile values) may be associated with different YANG types (e.g., decimal64 and yang:gauge64). To easily distinguish the types of these parameters while using meaningful names, the following suffixes are used:

Suffix	YANG Type	Example
-g	yang:gauge64	low-percentile-g
-c	container	connection-c
-ps	per second	connection-ps

Table 1: Suffixes and YANG Types

The full tree diagram of the DOTS telemetry module can be generated using the "pyang" tool [PYANG]. That tree is not included here because it is too long (Section 3.3 of [RFC8340]). Instead, subtrees are provided for the reader's convenience.

In order to optimize the data exchanged over the DOTS signal channel, this document specifies a second YANG module ("ietf-dots-mapping"; see Section 11.2) that augments the DOTS data channel [RFC8783]. This augmentation can be used during 'idle' time to share the attack mapping details (Section 8.1.5). DOTS clients can use tools, e.g., the YANG Library [RFC8525], to retrieve the list of features and deviations supported by the DOTS server over the data channel.

## 5. Generic Considerations

### 5.1. DOTS Client Identification

Following the rules in Section 4.4.1 of [RFC9132], a unique identifier is generated by a DOTS client to prevent request collisions ('cuid').

As a reminder, Section 4.4.1.3 of [RFC9132] forbids 'cuid' to be returned in a response message body.

### 5.2. DOTS Gateways

DOTS gateways may be located between DOTS clients and servers. The considerations elaborated in Section 4.4.1 of [RFC9132] must be followed. In particular, the 'cdid' attribute is used to unambiguously identify a DOTS client domain.

As a reminder, Section 4.4.1.3 of [RFC9132] forbids 'cdid' (if present) to be returned in a response message body.

### 5.3. Uri-Path Parameters and Empty Values

Uri-Path parameters and attributes with empty values MUST NOT be present in a request. The presence of such an empty value renders the entire containing message invalid.

### 5.4. Controlling Configuration Data

The DOTS server follows the same considerations discussed in Section 4.5.3 of [RFC9132] for managing DOTS telemetry configuration

freshness and notifications.

Likewise, a DOTS client may control the selection of configuration and non-configuration data nodes when sending a GET request by means of the 'c' (content) Uri-Query option and following the procedure specified in Section 4.4.2 of [RFC9132]. These considerations are not reiterated in the following sections.

## 5.5. Message Validation

The authoritative references for validating telemetry messages exchanged over the DOTS signal channel are Sections 7, 8, and 9 together with the mapping table provided in Section 12. The structure of telemetry message bodies is represented as a YANG data structure (Section 11.1).

## 5.6. A Note about Examples

Examples are provided for illustration purposes. This document does not aim to provide a comprehensive list of message examples.

JSON encoding of YANG-modeled data is used to illustrate the various telemetry operations. To ease readability, parameter names and their JSON types are thus used in the examples rather than their CBOR key values and CBOR types following the mappings in Section 12. These conventions are inherited from [RFC9132].

The examples use Enterprise Number 32473, which is defined for documentation use; see [RFC5612].

## 6. Telemetry Operation Paths

As discussed in Section 4.2 of [RFC9132], each DOTS operation is indicated by a path suffix that indicates the intended operation. The operation path is appended to the path prefix to form the URI used with a CoAP request to perform the desired DOTS operation. The following telemetry path suffixes are defined (Table 2):

Operation	Operation Path	Details
Telemetry Setup	/tm-setup	Section 7
Telemetry	/tm	Section 8

Table 2: DOTS Telemetry Operations

Consequently, the "ietf-dots-telemetry" YANG module defined in Section 11.1 defines a data structure to represent new DOTS message types called 'telemetry-setup' and 'telemetry'. The tree structure is shown in Figure 1. More details are provided in Sections 7 and 8 about the exact structure of 'telemetry-setup' and 'telemetry' message types.

structure dots-telemetry:

flow data as a distribution and describing that distribution entails choosing a measurement period that the distribution will describe, and a number of sampling intervals, or "buckets", within that measurement period. Traffic within each bucket is treated as a single event (i.e., averaged), and then the distribution of buckets is used to describe the distribution of traffic over the measurement period. A distribution can be characterized by statistical measures (e.g., mean, median, and standard deviation) and also by reporting the value of the distribution at various percentile levels of the data set in question (e.g., "quartiles" that correspond to 25th, 50th, and 75th percentiles). More details about percentile values and their computation are found in Section 11.3 of [RFC2330].

DOTS telemetry uses up to three percentile values, plus the overall peak, to characterize traffic distributions. Which percentile thresholds are used for these "low-percentile", "mid-percentile", and "high-percentile" values is configurable. Default values are defined in Section 7.1.2.

A DOTS client can negotiate with its server(s) a set of telemetry configuration parameters to be used for telemetry. Such parameters include:

- \* Percentile-related measurement parameters. In particular, 'measurement-interval' defines the period during which percentiles are computed, while 'measurement-sample' defines the time distribution for measuring values that are used to compute percentiles.
- \* Measurement units.
- \* Acceptable percentile values.
- \* Telemetry notification interval.
- \* Acceptable server-originated telemetry.

#### 7.1.1. Retrieving the Current DOTS Telemetry Configuration

A GET request is used to obtain acceptable and current telemetry configuration parameters on the DOTS server. This request may include a 'cdid' Uri-Path when the request is relayed by a DOTS gateway. An example of such a GET request (without a gateway) is depicted in Figure 2.

```
Header: GET (Code=0.01)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
```

Figure 2: GET to Retrieve the Current and Acceptable DOTS Telemetry Configuration

Upon receipt of such a request, and assuming that no error is encountered when processing the request, the DOTS server replies with

a 2.05 (Content) response that conveys the telemetry parameters that are acceptable to the DOTS server, any pipe information (Section 7.2), and the current baseline information (Section 7.3) maintained by the DOTS server for this DOTS client. The tree structure of the response message body is provided in Figure 3.

DOTS servers that support the capability of sending telemetry information to DOTS clients prior to or during a mitigation (Section 9.2) set 'server-originated-telemetry' under 'max-config-values' to 'true' ('false' is used otherwise). If 'server-originated-telemetry' is not present in a response, this is equivalent to receiving a response with 'server-originated-telemetry' set to 'false'.

```

structure dots-telemetry:

```

Figure 3: Telemetry Configuration Tree Structure

When both 'min-config-values' and 'max-config-values' attributes are present, the values carried in 'max-config-values' attributes MUST be greater than or equal to their counterparts in 'min-config-values' attributes.

### 7.1.2. Conveying the DOTS Telemetry Configuration

A PUT request is used to convey the configuration parameters for the telemetry data (e.g., low-, mid-, or high-percentile values). For example, a DOTS client may contact its DOTS server to change the default percentile values used as the baseline for telemetry data. Figure 3 lists the attributes that can be set by a DOTS client in such a PUT request. An example of a DOTS client that modifies all percentile reference values is shown in Figure 4.

Note: The payload of the message depicted in Figure 4 is CBOR-encoded as indicated by setting the Content-Format entry to "application/dots+cbor" (Section 10.3 of [RFC9132]). However, and for the sake of better readability, the example (and other similar figures depicting a DOTS telemetry message body) follows the conventions set in Section 5.6: use the JSON names and types defined in Section 12.

```

Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=123"
Content-Format: "application/dots+cbor"

{
  "ietf-dots-telemetry:telemetry-setup": {
    "telemetry": [
      {
        "current-config": {
          "low-percentile": "5.00",
          "mid-percentile": "65.00",
          "high-percentile": "95.00"
        }
      }
    ]
  }
}
  
```

Figure 4: PUT to Convey the DOTS Telemetry Configuration, Depicted as per Section 5.6

'cuid' is a mandatory Uri-Path parameter for PUT requests.

The following additional Uri-Path parameter is defined:

**tsid:** The Telemetry Setup Identifier is an identifier for the DOTS telemetry setup configuration data represented as an integer. This identifier **MUST** be generated by DOTS clients. 'tsid' values **MUST** increase monotonically whenever new configuration parameters (not just for changed values) need to be conveyed by the DOTS client.

The procedure specified in Section 4.4.1 of [RFC9132] for 'mid' rollover **MUST** also be followed for 'tsid' rollover.

This is a mandatory attribute. 'tsid' **MUST** appear after 'cuid' in the Uri-Path options.

'cuid' and 'tsid' **MUST NOT** appear in the PUT request message body.

At least one configurable attribute **MUST** be present in the PUT request.

A PUT request with a higher numeric 'tsid' value overrides the DOTS telemetry configuration data installed by a PUT request with a lower numeric 'tsid' value. To avoid maintaining a long list of 'tsid' requests for requests carrying telemetry configuration data from a DOTS client, the lower numeric 'tsid' **MUST** be automatically deleted and no longer be available at the DOTS server.

The DOTS server indicates the result of processing the PUT request using the following Response Codes:

- \* If the request is missing a mandatory attribute, does not include 'cuid' or 'tsid' Uri-Path parameters, or contains one or more invalid or unknown parameters, a 4.00 (Bad Request) Response Code **MUST** be returned in the response.
- \* If the DOTS server does not find the 'tsid' parameter value conveyed in the PUT request in its configuration data and if the DOTS server has accepted the configuration parameters, then a 2.01 (Created) Response Code **MUST** be returned in the response.
- \* If the DOTS server finds the 'tsid' parameter value conveyed in the PUT request in its configuration data and if the DOTS server has accepted the updated configuration parameters, a 2.04 (Changed) Response Code **MUST** be returned in the response.
- \* If any of the enclosed configurable attribute values are not acceptable to the DOTS server (Section 7.1.1), a 4.22 (Unprocessable Entity) Response Code **MUST** be returned in the response.

The DOTS client may retry and send the PUT request with updated attribute values acceptable to the DOTS server.

By default, low-percentile (10th percentile), mid-percentile (50th percentile), high-percentile (90th percentile), and peak (100th percentile) values are used to represent telemetry data. Nevertheless, a DOTS client can disable some percentile types (low, mid, high). In particular, setting 'low-percentile' to "0.00" indicates that the DOTS client is not interested in receiving low-percentiles. Likewise, setting 'mid-percentile' (or 'high-percentile') to the same value as 'low-percentile' (or 'mid-percentile') indicates that the DOTS client is not interested in receiving mid-percentiles (or high-percentiles). For example, a DOTS client can send the request depicted in Figure 5 to inform the server that it is interested in receiving only high-percentiles. This assumes that the client will only use that percentile type when sharing telemetry data with the server.

```
Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=124"
Content-Format: "application/dots+cbor"

{
  "ietf-dots-telemetry:telemetry-setup": {
    "telemetry": [
      {
        "current-config": {
          "low-percentile": "0.00",
          "mid-percentile": "0.00",
          "high-percentile": "95.00"
        }
      }
    ]
  }
}
```

Figure 5: PUT to Disable Low- and Mid-Percentiles, Depicted as per Section 5.6

DOTS clients can also configure the unit class(es) to be used for traffic-related telemetry data among the following supported unit classes: packets per second, bits per second, and bytes per second. Supplying both bits per second and bytes per second unit classes is allowed for a given set of telemetry data. However, receipt of conflicting values is treated as invalid parameters and rejected with a 4.00 (Bad Request) Response Code.

DOTS clients that are interested in receiving pre-or-ongoing-mitigation telemetry ('pre-or-ongoing-mitigation') information from a DOTS server (Section 9.2) MUST set 'server-originated-telemetry' to 'true'. If 'server-originated-telemetry' is not present in a PUT request, this is equivalent to receiving a request with 'server-originated-telemetry' set to 'false'. An example of a request to enable pre-or-ongoing-mitigation telemetry from DOTS servers is shown in Figure 6.

```

Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=125"
Content-Format: "application/dots+cbor"

{
  "ietf-dots-telemetry:telemetry-setup": {
    "telemetry": [
      {
        "current-config": {
          "server-originated-telemetry": true
        }
      }
    ]
  }
}

```

Figure 6: PUT to Enable Pre-or-Ongoing-Mitigation Telemetry from the DOTS Server, Depicted as per Section 5.6

#### 7.1.3. Retrieving the Installed DOTS Telemetry Configuration

A DOTS client may issue a GET message with a 'tsid' Uri-Path parameter to retrieve the current DOTS telemetry configuration. An example of such a request is depicted in Figure 7.

```

Header: GET (Code=0.01)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=123"

```

Figure 7: GET to Retrieve the Current DOTS Telemetry Configuration

If the DOTS server does not find the 'tsid' Uri-Path value conveyed in the GET request in its configuration data for the requesting DOTS client, it MUST respond with a 4.04 (Not Found) error Response Code.

#### 7.1.4. Deleting the DOTS Telemetry Configuration

A DELETE request is used to delete the installed DOTS telemetry configuration data (Figure 8). 'cuid' and 'tsid' are mandatory Uri-Path parameters for such DELETE requests.

```

Header: DELETE (Code=0.04)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=123"

```

Figure 8: Deleting the Telemetry Configuration

The DOTS server resets the DOTS telemetry configuration back to the default values and acknowledges a DOTS client's request to remove the DOTS telemetry configuration using a 2.02 (Deleted) Response Code. A 2.02 (Deleted) Response Code is returned even if the 'tsid' parameter value conveyed in the DELETE request does not exist in its configuration data before the request.

Section 7.4 discusses the procedure to reset all DOTS telemetry setup configuration data.

## 7.2. Total Pipe Capacity

A DOTS client can communicate to the DOTS server(s) its DOTS client domain pipe information. The tree structure of the pipe information is shown in Figure 9.

```
structure dots-telemetry:
  +-- (telemetry-message-type)?
  +--:(telemetry-setup)
  |
  |..
  | +-- telemetry* []
  |   +-- (direction)?
  |   |   +--:(server-to-client-only)
  |   |   +-- tsid?                                uint32
  |   +-- (setup-type)?
  |   |   +--:(telemetry-config)
  |   |   |..
  |   |   +--:(pipe)
  |   |   |   +-- total-pipe-capacity* [link-id unit]
  |   |   |   |   +-- link-id          nt:link-id
  |   |   |   |   +-- capacity        uint64
  |   |   |   |   +-- unit            unit
  |   |   +--:(baseline)
  |   |..
  | +--:(telemetry)
  |..
  +--:(telemetry)
  ...
```

Figure 9: Pipe Tree Structure

A DOTS client domain pipe is defined as a list of limits on (incoming) traffic volume ('total-pipe-capacity') that can be forwarded over ingress interconnection links of a DOTS client domain. Each of these links is identified with a 'link-id' [RFC8345].

The unit used by a DOTS client when conveying pipe information is captured in the 'unit' attribute. The DOTS client MUST auto-scale so that the appropriate unit is used. That is, for a given unit class, the DOTS client uses the largest unit that gives a value greater than one. As such, only one unit per unit class is allowed.

### 7.2.1. Conveying DOTS Client Domain Pipe Capacity

Considerations similar to those specified in Section 7.1.2 are followed, with one exception:

- \* The relative order of two PUT requests carrying DOTS client domain pipe attributes from a DOTS client is determined by comparing their respective 'tsid' values. If these two requests have overlapping 'link-id' and 'unit' settings, the PUT request with a higher numeric 'tsid' value will override the request with a lower numeric 'tsid' value. The overlapped lower numeric 'tsid' MUST be automatically deleted and no longer be available.

DOTS clients SHOULD minimize the number of active 'tsid's used for pipe information. In order to avoid maintaining a long list of 'tsid's for pipe information, it is RECOMMENDED that DOTS clients include in any request to update information related to a given link the information regarding other links (already communicated using a lower 'tsid' value). By doing so, this update request will override these existing requests and hence optimize the number of 'tsid' requests per DOTS client.

| Note: This assumes that all link information can fit in one single message.

As an example of configuring pipe information, a DOTS client managing a single-homed domain (Figure 10) can send a PUT request (shown in Figure 11) to communicate the capacity of "link1" used to connect to its ISP.

Figure 10: Single-Homed DOTS Client Domain

```

Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=126"
Content-Format: "application/dots+cbor"
  
```

```

{
  "ietf-dots-telemetry:telemetry-setup": {
    "telemetry": [
      {
        "total-pipe-capacity": [
          {
            "link-id": "link1",
            "capacity": "500",
            "unit": "megabit-ps"
          }
        ]
      }
    ]
  }
}
  
```

}

Figure 11: Example of a PUT Request to Convey Pipe Information (Single-Homed), Depicted as per Section 5.6

DOTS clients may be instructed to signal a link aggregate instead of individual links. For example, a DOTS client that manages a DOTS client domain having two interconnection links with an upstream ISP (Figure 12) can send a PUT request (shown in Figure 13) to communicate the aggregate link capacity with its ISP. Signaling individual or aggregate link capacity is deployment specific.

Figure 12: DOTS Client Domain with Two Interconnection Links

```
Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=hmcpH87lmPGsSTjkhXCbin"
Uri-Path: "tsid=896"
Content-Format: "application/dots+cbor"

{
  "ietf-dots-telemetry:telemetry-setup": {
    "telemetry": [
      {
        "total-pipe-capacity": [
          {
            "link-id": "aggregate",
            "capacity": "700",
            "unit": "megabit-ps"
          }
        ]
      }
    ]
  }
}
```

Figure 13: Example of a PUT Request to Convey Pipe Information (Aggregated Link), Depicted as per Section 5.6

Now consider that the DOTS client domain was upgraded to connect to an additional ISP (e.g., ISP#B in Figure 14); the DOTS client can inform a DOTS server that is not hosted with ISP#A and ISP#B domains about this update by sending the PUT request depicted in Figure 15. This request also includes information related to "link1" even if that link is not upgraded. Upon receipt of this request, the DOTS server removes the request with 'tsid=126' and updates its configuration base to maintain two links (link1 and link2).

Figure 14: Multihomed DOTS Client Domain

```

Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm-setup"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tsid=127"
Content-Format: "application/dots+cbor"

{
  "ietf-dots-telemetry:telemetry-setup": {
    "telemetry": [
      {
        "total-pipe-capacity": [
          {
            "link-id": "link1",
            "capacity": "500",
            "unit": "megabit-ps"
          },
          {
            "link-id": "link2",
            "capacity": "500",
            "unit": "megabit-ps"
          }
        ]
      }
    ]
  }
}
  
```

Figure 15: Example of a PUT Request to Convey Pipe Information (Multihomed), Depicted as per Section 5.6

A DOTS client can delete a link by sending a PUT request with the 'capacity' attribute set to "0" if other links are still active for the same DOTS client domain. For example, if a DOTS client domain re-homes (that is, it changes its ISP), the DOTS client can inform its DOTS server about this update (e.g., from the network configuration in Figure 10 to the network configuration shown in Figure 16) by sending the PUT request depicted in Figure 17. Upon receipt of this request, and assuming that no error is encountered when processing the request, the DOTS server removes "link1" from its

configuration bases for this DOTS client domain. Note that if the DOTS server receives a PUT request with a 'capacity' attribute set to "0" for all included links, it MUST reject the request with a 4.00 (Bad Request) Response Code. Instead, the DOTS client can use a DELETE request to delete all links (Section 7.2.3).

Figure 16: Multihomed DOTS Client Domain

```

Uri-Path: "tsid=128"
Content-Format: "application/dots+cbor"

{
  "ietf-dots-telemetry:telemetry-setup": {
    "telemetry": [
      {
        "total-pipe-capacity": [
          {
            "link-id": "link1",
            "capacity": "0",
            "unit": "megabit-ps"
          },
          {
            "link-id": "link2",
            "capacity": "500",
            "unit": "megabit-ps"
          }
        ]
      }
    ]
  }
}
  
```

Figure 17: Example of a PUT Request to Convey Pipe Information (Multihomed), Depicted as per Section 5.6

### 7.2.2. Retrieving Installed DOTS Client Domain Pipe Capacity

A GET request with a 'tsid' Uri-Path parameter is used to retrieve

the specific information related to an installed DOTS client domain pipe. The same procedure as that defined in Section 7.1.3 is followed.

To retrieve all pipe information bound to a DOTS client, the DOTS client proceeds as specified in Section 7.1.1.

### 7.2.3. Deleting Installed DOTS Client Domain Pipe Capacity

A DELETE request is used to delete the specific information related to an installed DOTS client domain pipe. The same procedure as that defined in Section 7.1.4 is followed.

## 7.3. Telemetry Baseline

A DOTS client can communicate to its DOTS server(s) its normal traffic baseline and connection capacity:

**Total traffic normal baseline:** Total traffic normal baseline data provides the percentile values representing the total traffic normal baseline. It can be represented for a target using 'total-traffic-normal'.

The traffic normal per-protocol ('total-traffic-normal-per-protocol') baseline is represented for a target and is transport-protocol specific.

The traffic normal per-port-number ('total-traffic-normal-per-port') baseline is represented for each port number bound to a target.

If the DOTS client negotiated percentile values and units (Section 7.1), these negotiated parameters will be used instead of the default parameters. For each unit class used, the DOTS client MUST auto-scale so that the appropriate unit is used.

**Total connection capacity:** If the target is susceptible to resource-consuming DDoS attacks, the following optional attributes for the target per transport protocol are useful for detecting resource-consuming DDoS attacks:

- \* The maximum number of simultaneous connections that are allowed to the target.
- \* The maximum number of simultaneous connections that are allowed to the target per client.
- \* The maximum number of simultaneous embryonic connections that are allowed to the target. The term "embryonic connection" refers to a connection whose connection handshake is not finished. Embryonic connections are only possible in connection-oriented transport protocols like TCP or the Stream Control Transmission Protocol (SCTP) [RFC9260].
- \* The maximum number of simultaneous embryonic connections that are allowed to the target per client.

- \* The maximum number of connections allowed per second to the target.
- \* The maximum number of connections allowed per second to the target per client.
- \* The maximum number of requests (e.g., HTTP/DNS/SIP requests) allowed per second to the target.
- \* The maximum number of requests allowed per second to the target per client.
- \* The maximum number of outstanding partial requests allowed to the target. Attacks relying upon partial requests create a connection with a target but do not send a complete request (e.g., an HTTP request).
- \* The maximum number of outstanding partial requests allowed to the target per client.

The aggregate per transport protocol is captured in 'total-connection-capacity', while port-specific capabilities are represented using 'total-connection-capacity-per-port'.

Note that a target resource is identified using the attributes 'target-prefix', 'target-port-range', 'target-protocol', 'target-fqdn', 'target-uri', or 'alias-name' as defined in Section 4.4.1.1 of [RFC9132].

The tree structure of the normal traffic baseline is shown in Figure 18.

Figure 18: Telemetry Baseline Tree Structure

A DOTS client can share one or multiple normal traffic baselines (e.g., aggregate or per-prefix baselines); each is uniquely identified within the DOTS client domain with an identifier ('id'). This identifier can be used to update a baseline entry, delete a specific entry, etc.

### 7.3.1. Conveying DOTS Client Domain Baseline Information

Considerations similar to those specified in Section 7.1.2 are followed, with one exception:

- \* The relative order of two PUT requests carrying DOTS client domain baseline attributes from a DOTS client is determined by comparing their respective 'tsid' values. If these two requests have overlapping targets, the PUT request with a higher numeric 'tsid' value will override the request with a lower numeric 'tsid' value. The overlapped lower numeric 'tsid' MUST be automatically deleted and no longer be available.

Two PUT requests from a DOTS client have overlapping targets if there is a common IP address, IP prefix, FQDN, URI, or alias name. Also, two PUT requests from a DOTS client have overlapping targets from the perspective of the DOTS server if the addresses associated with the FQDN, URI, or alias are overlapping with each other or with 'target-prefix'.

DOTS clients SHOULD minimize the number of active 'tsid's used for baseline information. In order to avoid maintaining a long list of 'tsid's for baseline information, it is RECOMMENDED that DOTS clients include in any request to update information related to a given target the information regarding other targets (already communicated using a lower 'tsid' value) (assuming that this information fits within one single datagram). This update request will override these existing requests and hence optimize the number of 'tsid' requests per DOTS client.

If no target attribute is included in the request, this is an indication that the baseline information applies for the DOTS client domain as a whole.

An example of a PUT request to convey the baseline information is shown in Figure 19.

```

                "protocol": 17,
                "peak-g": "10"
              }
            ]
          }
        ]
      }
    ]
  }
}

```

1: Overlapping targets (Section 4.4.1 of [RFC9132]).

5: Overlapping pipe scope (see Section 13).

## 8. DOTS Pre-or-Ongoing-Mitigation Telemetry

There are two broad types of DDoS attacks: bandwidth-consuming attacks and target-resource-consuming attacks. This section outlines the set of DOTS telemetry attributes (Section 8.1) that covers both types of attacks. The objective of these attributes is to allow for the complete knowledge of attacks and the various particulars that can best characterize attacks.

The "ietf-dots-telemetry" YANG module (Section 11.1) defines the data structure of a new message type called 'telemetry'. The tree structure of the 'telemetry' message type is shown in Figure 22.

```
structure dots-telemetry:
  +-- (telemetry-message-type)?
    +--:(telemetry-setup)
      |
      |..
      +-- telemetry* []
        +-- (direction)?
          | +--:(server-to-client-only)
          |   +-- tsid?                               uint32
        +-- (setup-type)?
          +--:(telemetry-config)
            |..
            +--:(pipe)
            |..
            +--:(baseline)
            |..
    +--:(telemetry)
      +-- pre-or-ongoing-mitigation* []
        +-- (direction)?
          | +--:(server-to-client-only)
          |   +-- tmid?                               uint32
        +-- target
          |..
        +-- total-traffic* [unit]
          |..
        +-- total-traffic-protocol* [unit protocol]
          |..
        +-- total-traffic-port* [unit port]
          |..
        +-- total-attack-traffic* [unit]
          |..
        +-- total-attack-traffic-protocol* [unit protocol]
          |..
        +-- total-attack-traffic-port* [unit port]
          |..
        +-- total-attack-connection-protocol* [protocol]
          |..
        +-- total-attack-connection-port* [protocol port]
          |..
        +-- attack-detail* [vendor-id attack-id]
```

...

Figure 22: Telemetry Message Type Tree Structure

The pre-or-ongoing-mitigation telemetry attributes are indicated by the path suffix '/tm'. '/tm' is appended to the path prefix to form the URI used with a CoAP request to signal the DOTS telemetry. Pre-or-ongoing-mitigation telemetry attributes as specified in Section 8.1 can be signaled between DOTS agents.

Pre-or-ongoing-mitigation telemetry attributes may be sent by a DOTS client or a DOTS server.

DOTS agents SHOULD bind pre-or-ongoing-mitigation telemetry data to mitigation requests associated with the resources under attack. In particular, a telemetry PUT request sent after a mitigation request may include a reference to that mitigation request ('mid-list') as shown in Figure 23. An example illustrating request correlation by means of 'target-prefix' is shown in Figure 24.

Much of the pre-or-ongoing-mitigation telemetry data uses a unit that falls under the unit class that is configured following the procedure described in Section 7.1.2. When generating telemetry data to send to a peer, the DOTS agent MUST auto-scale so that one or more appropriate units are used.

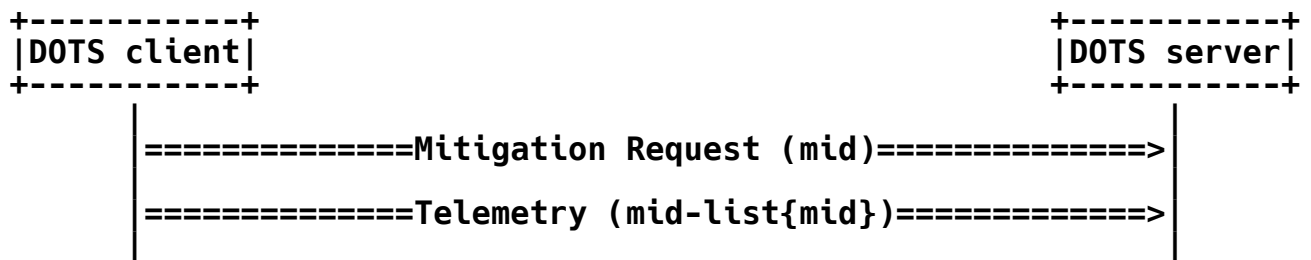

Figure 23: Example of Request Correlation Using 'mid'

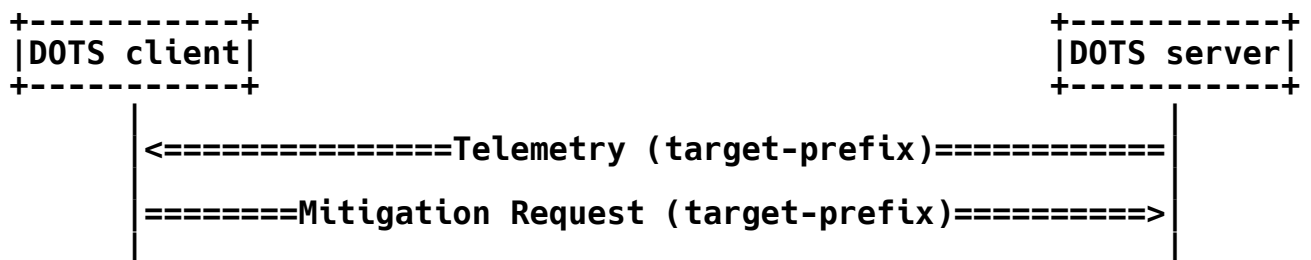

Figure 24: Example of Request Correlation Using 'target-prefix'

DOTS agents MUST NOT send pre-or-ongoing-mitigation telemetry notifications to the same peer more frequently than once every 'telemetry-notify-interval' (Section 7.1). If a telemetry notification is sent using a block-like transfer mechanism (e.g., [RFC9177]), this rate-limit policy MUST NOT consider these individual blocks as separate notifications, but as a single notification.

DOTS pre-or-ongoing-mitigation telemetry request and response

messages MUST be marked as Non-confirmable messages (Section 2.1 of [RFC7252]).

## 8.1. Pre-or-Ongoing-Mitigation DOTS Telemetry Attributes

Section 3 discusses the motivation for using the DOTS telemetry attributes. These attributes are specified in the following subsections.

### 8.1.1. Target

A target resource (Figure 25) is identified using the attributes 'target-prefix', 'target-port-range', 'target-protocol', 'target-fqdn', 'target-uri', 'alias-name', or a pointer to a mitigation request ('mid-list').

```
+--:(telemetry)
  +-- pre-or-ongoing-mitigation* []
    +-- (direction)?
      +--:(server-to-client-only)
        +-- tmid?                               uint32
      +-- target
        +-- target-prefix*                       inet:ip-prefix
        +-- target-port-range* [lower-port]
          +-- lower-port                       inet:port-number
          +-- upper-port?                     inet:port-number
        +-- target-protocol*                     uint8
        +-- target-fqdn*                         inet:domain-name
        +-- target-uri*                         inet:uri
        +-- alias-name*                         string
        +-- mid-list*                           uint32
      +-- total-traffic* [unit]
        ...
      +-- total-traffic-protocol* [unit protocol]
        ...
      +-- total-traffic-port* [unit port]
        ...
      +-- total-attack-traffic* [unit]
        ...
      +-- total-attack-traffic-protocol* [unit protocol]
        ...
      +-- total-attack-traffic-port* [unit port]
        ...
      +-- total-attack-connection-protocol* [protocol]
        ...
      +-- total-attack-connection-port* [protocol port]
        ...
      +-- attack-detail* [vendor-id attack-id]
        ...
```

Figure 25: Target Tree Structure

At least one of the attributes 'target-prefix', 'target-fqdn', 'target-uri', 'alias-name', or 'mid-list' MUST be present in the target definition.

If the target is susceptible to bandwidth-consuming attacks, the attributes representing the percentile values of the 'attack-id' attack traffic are included.

If the target is susceptible to resource-consuming DDoS attacks, the attributes defined in Section 8.1.4 are applicable for representing the attack.

At least the 'target' attribute and one other pre-or-ongoing-mitigation attribute **MUST** be present in the DOTS telemetry message.

### 8.1.2. Total Traffic

The 'total-traffic' attribute (Figure 26) conveys the percentile values (including peak and current observed values) of the total observed traffic. More fine-grained information about the total traffic can be conveyed in the 'total-traffic-protocol' and 'total-traffic-port' attributes.

The 'total-traffic-protocol' attribute represents the total traffic for a target and is transport-protocol specific.

The 'total-traffic-port' attribute represents the total traffic for a target per port number.

```
+--:(telemetry)
  +-- pre-or-ongoing-mitigation* []
    +-- (direction)?
      +--:(server-to-client-only)
        +-- tmid?                               uint32
      +-- target
      +-- ...
    +-- total-traffic* [unit]
      +-- unit                                   unit
      +-- low-percentile-g?                     yang:gauge64
      +-- mid-percentile-g?                     yang:gauge64
      +-- high-percentile-g?                   yang:gauge64
      +-- peak-g?                              yang:gauge64
      +-- current-g?                           yang:gauge64
    +-- total-traffic-protocol* [unit protocol]
      +-- protocol                             uint8
      +-- unit                                   unit
      +-- low-percentile-g?                     yang:gauge64
      +-- mid-percentile-g?                     yang:gauge64
      +-- high-percentile-g?                   yang:gauge64
      +-- peak-g?                              yang:gauge64
      +-- current-g?                           yang:gauge64
    +-- total-traffic-port* [unit port]
      +-- port                                 inet:port-number
      +-- unit                                   unit
      +-- low-percentile-g?                     yang:gauge64
      +-- mid-percentile-g?                     yang:gauge64
      +-- high-percentile-g?                   yang:gauge64
      +-- peak-g?                              yang:gauge64
      +-- current-g?                           yang:gauge64
    +-- total-attack-traffic* [unit]
```

```

|   ...

+-- attack-detail* [vendor-id attack-id]
|   ...

```

Figure 26: Total Traffic Tree Structure

### 8.1.3. Total Attack Traffic

The 'total-attack-traffic' attribute (Figure 27) conveys the total observed attack traffic. More fine-grained information about the total attack traffic can be conveyed in the 'total-attack-traffic-protocol' and 'total-attack-traffic-port' attributes.

The 'total-attack-traffic-protocol' attribute represents the total attack traffic for a target and is transport-protocol specific.

The 'total-attack-traffic-port' attribute represents the total attack traffic for a target per port number.

```

+--:(telemetry)
+-- pre-or-ongoing-mitigation* []
+-- (direction)?
|   +--:(server-to-client-only)
|       +-- tmid?                               uint32
+-- target
|   ...
+-- total-traffic* [unit]
|   ...
+-- total-traffic-protocol* [unit protocol]
|   ...
+-- total-traffic-port* [unit port]
|   ...
+-- total-attack-traffic* [unit]
|   +-- unit                                     unit
|   +-- low-percentile-g?                       yang:gauge64
|   +-- mid-percentile-g?                      yang:gauge64
|   +-- high-percentile-g?                     yang:gauge64
|   +-- peak-g?                                yang:gauge64
|   +-- current-g?                             yang:gauge64
+-- total-attack-traffic-protocol* [unit protocol]
|   +-- protocol                               uint8
|   +-- unit                                   unit
|   +-- low-percentile-g?                     yang:gauge64
|   +-- mid-percentile-g?                     yang:gauge64
|   +-- high-percentile-g?                    yang:gauge64
|   +-- peak-g?                              yang:gauge64
|   +-- current-g?                           yang:gauge64
+-- total-attack-traffic-port* [unit port]

```

```

|   ...
+-- attack-detail* [vendor-id attack-id]
|   ...

```

Figure 27: Total Attack Traffic Tree Structure

#### 8.1.4. Total Attack Connections

If the target is susceptible to resource-consuming DDoS attacks, the 'total-attack-connection-protocol' attribute is used to convey the percentile values (including peak and current observed values) of various attributes related to the total attack connections. The following optional sub-attributes for the target per transport protocol are included to represent the attack characteristics:

- \* The number of simultaneous attack connections to the target.
- \* The number of simultaneous embryonic connections to the target.
- \* The number of attack connections per second to the target.
- \* The number of attack requests per second to the target.
- \* The number of attack partial requests to the target.

The total attack connections per port number are represented using the 'total-attack-connection-port' attribute.

```

+--:(telemetry)
  +-- pre-or-ongoing-mitigation* []
    +-- (direction)?
      +--:(server-to-client-only)
        +-- tmid?                               uint32
      +-- target
      |   ...

Figure 28: Total Attack Connections Tree Structure

#### 8.1.5. Attack Details

This attribute (depicted in Figure 29) is used to signal a set of details characterizing an attack. The following sub-attributes describing the ongoing attack can be signaled as attack details:

**vendor-id:** Vendor ID. This parameter represents a security vendor's enterprise number as registered in the IANA "Private Enterprise Numbers" registry [Private-Enterprise-Numbers].

**attack-id:** Unique identifier assigned for the attack by a vendor. This parameter **MUST** be present, independently of whether 'attack-description' is included or not.

**description-lang:** Indicates the language tag that is used for the text that is included in the 'attack-description' attribute. This attribute is encoded following the rules in Section 2.1 of [RFC5646]. The default language tag is "en-US".

**attack-description:** Textual representation of the attack description. This description is related to the class of attack rather than a specific instance of it. Natural Language Processing techniques (e.g., word embedding) might provide some utility in mapping the attack description to an attack type. Textual representation of an attack solves two problems: it avoids the need to (a) create mapping tables manually between vendors and (b) standardize attack types that keep evolving.

**attack-severity:** Attack severity level. This attribute takes one of the values defined in Section 3.12.2 of [RFC7970].

**start-time:** The time the attack started. The attack's start time is expressed in seconds relative to 1970-01-01T00:00Z (Section 3.4.2 of [RFC8949]). The CBOR encoding is modified so that the leading tag 1 (epoch-based date/time) **MUST** be omitted.

**end-time:** The time the attack ended. The attack's end time is expressed in seconds relative to 1970-01-01T00:00Z (Section 3.4.2 of [RFC8949]). The CBOR encoding is modified so that the leading tag 1 (epoch-based date/time) **MUST** be omitted.

**source-count:** A count of sources involved in the attack targeting the victim.

**top-talker:** A list of attack sources that are involved in an attack and that are generating an important part of the attack traffic. The top talkers are represented using 'source-prefix'.

'spoofed-status' indicates whether a top talker is a spoofed IP address (e.g., reflection attacks) or not. If no 'spoofed-status' data node is included, this means that the spoofing status is unknown.

If the target is being subjected to a bandwidth-consuming attack, a statistical profile of the attack traffic from each of the top talkers is included ('total-attack-traffic'; see Section 8.1.3).

If the target is being subjected to a resource-consuming DDoS attack, the same attributes as those defined in Section 8.1.4 are applicable for characterizing the attack on a per-talker basis.

```

Figure 29: Attack Details Tree Structure

In order to optimize the size of telemetry data conveyed over the DOTS signal channel, DOTS agents MAY use the DOTS data channel

[RFC8783] to exchange vendor-specific attack mapping details (that is, {vendor identifier, attack identifier} ==> textual representation of the attack description). As such, DOTS agents do not have to convey an attack description systematically in their telemetry messages over the DOTS signal channel. Refer to Section 8.1.6.

#### 8.1.6. Vendor Attack Mapping

Multiple mappings for different vendor identifiers may be used; the DOTS agent transmitting telemetry information can elect to use one or more vendor mappings even in the same telemetry message.

Note: It is possible that a DOTS server is making use of multiple DOTS mitigators, each from a different vendor. How telemetry information and vendor mappings are exchanged between DOTS servers and DOTS mitigators is outside the scope of this document.

DOTS clients and servers may be provided with mappings from different vendors and so have their own different sets of vendor attack mappings. A DOTS agent **MUST** accept receipt of telemetry data with a vendor identifier that is different than the identifier it uses to transmit telemetry data. Furthermore, it is possible that the DOTS client and DOTS server are provided by the same vendor but the vendor mapping tables are at different revisions. The DOTS client **SHOULD** transmit telemetry information using any vendor mapping(s) that it provided to the DOTS server (e.g., using a POST as depicted in Figure 30), and the DOTS server **SHOULD** use any vendor mappings(s) provided to the DOTS client when transmitting telemetry data to the peer DOTS agent.

```
POST /restconf/data/ietf-dots-data-channel:dots-data\
     /dots-client=dz6pHjaADkaFTbjr0JGBpw HTTP/1.1
Host: example.com
Content-Type: application/yang-data+json
```

```
{

          },
          {
            "attack-id": 2,
            "attack-description":
              "Again, include a description of the attack"
          }
        ]
      }
    ]
  }
}
```

```

    }
  ]
}

```

Figure 30: POST to Install Vendor Attack Mapping Details

The "ietf-dots-mapping" YANG module defined in Section 11.2 augments the "ietf-dots-data-channel" module [RFC8783]. The tree structure of the "ietf-dots-mapping" module is shown in Figure 31.

```

module: ietf-dots-mapping
  augment /data-channel:dots-data/data-channel:dots-client:
    +--rw vendor-mapping {dots-telemetry}?
      +--rw vendor* [vendor-id]
        +--rw vendor-id          uint32
        +--rw vendor-name?       string
        +--rw description-lang?   string
        +--rw last-updated        uint64
        +--rw attack-mapping* [attack-id]
          +--rw attack-id          uint32
          +--rw attack-description string
  augment /data-channel:dots-data/data-channel:capabilities:
    +--ro vendor-mapping-enabled? boolean {dots-telemetry}?
  augment /data-channel:dots-data:
    +--ro vendor-mapping {dots-telemetry}?
      +--ro vendor* [vendor-id]
        +--ro vendor-id          uint32
        +--ro vendor-name?       string
        +--ro description-lang?   string
        +--ro last-updated        uint64
        +--ro attack-mapping* [attack-id]
          +--ro attack-id          uint32
          +--ro attack-description string

```

Figure 31: Vendor Attack Mapping Tree Structure

A DOTS client sends a GET request over the DOTS data channel to retrieve the capabilities supported by a DOTS server as per Section 7.1 of [RFC8783]. This request is meant to assess whether the capability of sharing vendor attack mapping details is supported by the server (i.e., check the value of 'vendor-mapping-enabled').

If 'vendor-mapping-enabled' is set to 'true', a DOTS client MAY send a GET request to retrieve the DOTS server's vendor attack mapping details. An example of such a GET request is shown in Figure 32.

```

GET /restconf/data/ietf-dots-data-channel:dots-data\
  /ietf-dots-mapping:vendor-mapping HTTP/1.1
Host: example.com
Accept: application/yang-data+json

```

Figure 32: GET to Retrieve the Vendor Attack Mappings of a DOTS Server

A DOTS client can retrieve only the list of vendors supported by the DOTS server. It does so by setting the "depth" parameter

(Section 4.8.2 of [RFC8040]) to "3" in the GET request as shown in Figure 33. An example of a response body received from the DOTS server as a response to such a request is illustrated in Figure 34.

```
GET /restconf/data/ietf-dots-data-channel:dots-data\
    /ietf-dots-mapping:vendor-mapping?depth=3 HTTP/1.1
Host: example.com
Accept: application/yang-data+json
```

Figure 33: GET to Retrieve the Vendors List Used by a DOTS Server

```
{
  "ietf-dots-mapping:vendor-mapping": {
    "vendor": [
      {
        "vendor-id": 32473,
        "vendor-name": "mitigator-s",
        "last-updated": "1629898758",
        "attack-mapping": []
      }
    ]
  }
}
```

Figure 34: Response Message Body to a GET to Retrieve the Vendors List Used by a DOTS Server

The DOTS client repeats the above procedure regularly (e.g., once a week) to update the DOTS server's vendor attack mapping details.

If the DOTS client concludes that the DOTS server does not have any reference to the specific vendor attack mapping details, the DOTS client uses a POST request to install its vendor attack mapping details. An example of such a POST request is depicted in Figure 30.

The DOTS server indicates the result of processing the POST request using the status-line. A "201 Created" status-line MUST be returned in the response if the DOTS server has accepted the vendor attack mapping details. If the request is missing a mandatory attribute or contains an invalid or unknown parameter, a "400 Bad Request" status-line MUST be returned by the DOTS server in the response. The error-tag is set to "missing-attribute", "invalid-value", or "unknown-element" as a function of the encountered error.

If the request is received via a server-domain DOTS gateway but the DOTS server does not maintain a 'cdid' for this 'cuid' while a 'cdid' is expected to be supplied, the DOTS server MUST reply with a "403 Forbidden" status-line and the error-tag "access-denied". Upon receipt of this message, the DOTS client MUST register (Section 5.1 of [RFC8783]).

The DOTS client uses the PUT request to modify its vendor attack mapping details maintained by the DOTS server (e.g., add a new mapping entry, update an existing mapping).

A DOTS client uses a GET request to retrieve its vendor attack

mapping details as maintained by the DOTS server (Figure 35).

```
GET /restconf/data/ietf-dots-data-channel:dots-data\  
  /dots-client=dz6pHjaADkaFTbjr0JGBpw\  
  /ietf-dots-mapping:vendor-mapping?\  
  content=all HTTP/1.1  
Host: example.com  
Accept: application/yang-data+json
```

Figure 35: GET to Retrieve Installed Vendor Attack Mapping Details

When conveying attack details in DOTS telemetry messages (Sections 8.2, 8.3, and 9), DOTS agents **MUST NOT** include the 'attack-description' attribute unless the corresponding attack mapping details were not previously shared with the peer DOTS agent.

## 8.2. From DOTS Clients to DOTS Servers

DOTS clients use PUT requests to signal pre-or-ongoing-mitigation telemetry to DOTS servers. An example of such a request is shown in Figure 36.

```
Header: PUT (Code=0.03)  
Uri-Path: ".well-known"  
Uri-Path: "dots"  
Uri-Path: "tm"  
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"  
Uri-Path: "tmid=123"  
Content-Format: "application/dots+cbor"  
  
{  
  "ietf-dots-telemetry:telemetry": {  
    "pre-or-ongoing-mitigation": [  
      {  
        "target": {  
          "target-prefix": [  
            "2001:db8::1/128"  
          ]  
        },  
        "total-attack-traffic-protocol": [  
          {  
            "protocol": 17,  
            "unit": "megabit-ps",  
            "mid-percentile-g": "900"  
          }  
        ],  
        "attack-detail": [  
          {  
            "vendor-id": 32473,  
            "attack-id": 77,  
            "start-time": "1608336568",  
            "attack-severity": "high"  
          }  
        ]  
      }  
    ]  
  }  
}
```

```
}  
}
```

Figure 36: PUT to Send Pre-or-Ongoing-Mitigation Telemetry,  
Depicted as per Section 5.6

'cuid' is a mandatory Uri-Path parameter for DOTS PUT requests.

The following additional Uri-Path parameter is defined:

**tmid:** The Telemetry Identifier is an identifier for the DOTS pre-or-ongoing-mitigation telemetry data represented as an integer. This identifier **MUST** be generated by DOTS clients. 'tmid' values **MUST** increase monotonically whenever a DOTS client needs to convey a new set of pre-or-ongoing-mitigation telemetry data.

The procedure specified in Section 4.4.1 of [RFC9132] for 'mid' rollover **MUST** be followed for 'tmid' rollover.

This is a mandatory attribute. 'tmid' **MUST** appear after 'cuid' in the Uri-Path options.

'cuid' and 'tmid' **MUST NOT** appear in the PUT request message body.

At least the 'target' attribute and another pre-or-ongoing-mitigation attribute (Section 8.1) **MUST** be present in the PUT request. If only the 'target' attribute is present, this request is handled as per Section 8.3.

The relative order of two PUT requests carrying DOTS pre-or-ongoing-mitigation telemetry from a DOTS client is determined by comparing their respective 'tmid' values. If these two requests have an overlapping 'target', the PUT request with a higher numeric 'tmid' value will override the request with a lower numeric 'tmid' value. The overlapped lower numeric 'tmid' **MUST** be automatically deleted and no longer be available.

The DOTS server indicates the result of processing a PUT request using CoAP Response Codes. In particular, the 2.04 (Changed) Response Code is returned if the DOTS server has accepted the pre-or-ongoing-mitigation telemetry. The 5.03 (Service Unavailable) Response Code is returned if the DOTS server has erred. The 5.03 Response Code uses the Max-Age Option to indicate the number of seconds after which to retry.

How long a DOTS server maintains a 'tmid' as active or logs the enclosed telemetry information is implementation specific. Note that if a 'tmid' is still active, then logging details are updated by the DOTS server as a function of the updates received from the peer DOTS client.

A DOTS client that lost the state of its active 'tmid's or has to set 'tmid' back to zero (e.g., crash or restart) **MUST** send a GET request to the DOTS server to retrieve the list of active 'tmid' values. The DOTS client may then delete 'tmid's that should not be active anymore (Figure 37). Sending a DELETE with no 'tmid' indicates that all

'tmid's must be deactivated (Figure 38).

Figure 38: Deleting All Pre-or-Ongoing-Mitigation Telemetry Information

### 8.3. From DOTS Servers to DOTS Clients

The pre-or-ongoing-mitigation data (attack details in particular) can also be signaled from DOTS servers to DOTS clients. For example, a DOTS server co-located with a DDoS detector can collect monitoring information from the target network, identify a DDoS attack using statistical analysis or deep learning techniques, and signal the attack details to the DOTS client.

The DOTS client can use the attack details to decide whether to trigger a DOTS mitigation request or not. Furthermore, the security operations personnel at the DOTS client domain can use the attack details to determine the protection strategy and select the appropriate DOTS server for mitigating the attack.

In order to receive pre-or-ongoing-mitigation telemetry notifications from a DOTS server, a DOTS client MUST send a PUT (followed by a GET) with the target filter. An example of such a PUT request is shown in Figure 39. In order to avoid maintaining a long list of such requests, it is RECOMMENDED that DOTS clients include all targets in the same request (assuming that this information fits within one single datagram). DOTS servers may be instructed to restrict the number of pre-or-ongoing-mitigation requests per DOTS client domain. The pre-or-ongoing-mitigation requests MUST be maintained in an active state by the DOTS server until a DELETE request is received from the same DOTS client to clear this pre-or-ongoing-mitigation telemetry or when the DOTS client is considered inactive (e.g., Section 3.5 of [RFC8783]).

The relative order of two PUT requests carrying DOTS pre-or-ongoing-mitigation telemetry from a DOTS client is determined by comparing their respective 'tmid' values. If these two requests have an overlapping 'target', the PUT request with a higher numeric 'tmid' value will override the request with a lower numeric 'tmid' value. The overlapped lower numeric 'tmid' MUST be automatically deleted and

no longer be available.

```
Header: PUT (Code=0.03)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm"

    "pre-or-ongoing-mitigation": [
      {
        "target": {
          "target-prefix": [
            "2001:db8::/32"
          ]
        }
      }
    ]
  }
}
```

Figure 39: PUT to Request Pre-or-Ongoing-Mitigation Telemetry, Depicted as per Section 5.6

DOTS clients of the same domain can ask to receive pre-or-ongoing-mitigation telemetry bound to the same target without being considered to be "overlapping" and in conflict.

Once the PUT request to instantiate request state on the server has succeeded, the DOTS client issues a GET request to receive ongoing telemetry updates. The client uses the Observe Option, set to "0" (register), in the GET request to receive asynchronous notifications carrying pre-or-ongoing-mitigation telemetry data from the DOTS server. The GET request can specify a specific 'tmid' (Figure 40) or omit the 'tmid' (Figure 41) to receive updates on all active requests from that client.

```
Header: GET (Code=0.01)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "tmid=567"
Observe: 0
```

Figure 40: GET to Subscribe to Telemetry Asynchronous Notifications for a Specific 'tmid'

```
Header: GET (Code=0.01)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
```

Observe: 0

Figure 41: GET to Subscribe to Telemetry Asynchronous Notifications for All 'tmid's

The DOTS client can use a filter to request a subset of the asynchronous notifications from the DOTS server by indicating one or more Uri-Query options in its GET request. A Uri-Query option can include the following parameters to restrict the notifications based on the attack target: 'target-prefix', 'target-port', 'target-protocol', 'target-fqdn', 'target-uri', 'alias-name', 'mid', and 'c' (content) (Section 5.4). Furthermore:

- \* If more than one Uri-Query option is included in a request, these options are interpreted in the same way as when multiple target attributes are included in a message body (Section 4.4.1 of [RFC9132]).
- \* If multiple values of a query parameter are to be included in a request, these values MUST be included in the same Uri-Query option and separated by a "," character without any spaces.
- \* Range values (i.e., a contiguous inclusive block) can be included for the 'target-port', 'target-protocol', and 'mid' parameters by indicating the two boundary values separated by a "-" character.
- \* Wildcard names (i.e., a name with the leftmost label is the "\*" character) can be included in 'target-fqdn' or 'target-uri' parameters. DOTS clients MUST NOT include a name in which the "\*" character is included in a label other than the leftmost label. "\*.example.com" is an example of a valid wildcard name that can be included as a value of the 'target-fqdn' parameter in a Uri-Query option.

DOTS clients may also filter out the asynchronous notifications from the DOTS server by indicating information about a specific attack source. To that aim, a DOTS client may include 'source-prefix', 'source-port', or 'source-icmp-type' in a Uri-Query option. The same considerations (ranges, multiple values) specified for target attributes apply for source attributes. Special care SHOULD be taken when using these filters, as their use may cause some attacks to be hidden from the requesting DOTS client (e.g., if the attack changes its source information).

Requests with invalid query types (e.g., not supported, malformed) received by the DOTS server MUST be rejected with a 4.00 (Bad Request) Response Code.

An example of a request to subscribe to asynchronous telemetry notifications regarding UDP traffic is shown in Figure 42. This filter will be applied for all 'tmid's.

```
Header: GET (Code=0.01)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "tm"
```

Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"  
Uri-Query: "target-protocol=17"  
Observe: 0

Figure 42: GET Request to Receive Telemetry Asynchronous Notifications Filtered Using Uri-Query

The DOTS server will send asynchronous notifications to the DOTS client when an attack event is detected, following considerations similar to those discussed in Section 4.4.2.1 of [RFC9132]. An example of a pre-or-ongoing-mitigation telemetry notification is shown in Figure 43.

```
{
  "ietf-dots-telemetry:telemetry": {
    "pre-or-ongoing-mitigation": [
      {
        "tmid": 567,
        "target": {
          "target-prefix": [
            "2001:db8::1/128"
          ]
        },
        "target-protocol": [
          17
        ],
        "total-attack-traffic": [
          {
            "unit": "megabit-ps",
            "mid-percentile-g": "900"
          }
        ],
        "attack-detail": [
          {
            "vendor-id": 32473,
            "attack-id": 77,
            "start-time": "1618339785",
            "attack-severity": "high"
          }
        ]
      }
    ]
  }
}
```

Figure 43: Message Body of a Pre-or-Ongoing-Mitigation Telemetry Notification from the DOTS Server, Depicted as per Section 5.6

A DOTS server sends the aggregate data for a target using the 'total-attack-traffic' attribute. The aggregate assumes that Uri-Query filters are applied on the target. The DOTS server MAY include more fine-grained data when needed (that is, 'total-attack-traffic-protocol' and 'total-attack-traffic-port'). If a port filter (or protocol filter) is included in a request, 'total-attack-traffic-protocol' (or 'total-attack-traffic-port') conveys the data with the port (or protocol) filter applied.

A DOTS server may aggregate pre-or-ongoing-mitigation data (e.g., 'top-talker') for all targets of a domain or, when justified, send specific information (e.g., 'top-talker') for a specific target.

The DOTS client may log pre-or-ongoing-mitigation telemetry data with an alert sent to an administrator or a network controller. The DOTS client may send a mitigation request if the attack cannot be handled locally.

A DOTS client that is not interested in receiving pre-or-ongoing-mitigation telemetry data for a target sends a DELETE request similar to the DELETE request depicted in Figure 37.

## 9. DOTS Telemetry Mitigation Status Update

### 9.1. From DOTS Clients to DOTS Servers: Mitigation Efficacy DOTS Telemetry Attributes

The mitigation efficacy telemetry attributes can be signaled from DOTS clients to DOTS servers as part of the periodic mitigation efficacy updates to the server (Section 4.4.3 of [RFC9132]).

**Total attack traffic:** The overall attack traffic as observed from the DOTS client's perspective during an active mitigation. See Figure 27.

**Attack details:** The overall attack details as observed from the DOTS client's perspective during an active mitigation. See Section 8.1.5.

The "ietf-dots-telemetry" YANG module (Section 11.1) augments the 'mitigation-scope' message type defined in the "ietf-dots-signal-channel" module [RFC9132] so that these attributes can be signaled by a DOTS client in a mitigation efficacy update (Figure 44).

```
augment-structure /dots-signal:dots-signal/dots-signal:message-type
                  /dots-signal:mitigation-scope/dots-signal:scope:
+-- total-attack-traffic* [unit]

                |   ...

```

Figure 44: Telemetry Efficacy Update Tree Structure

In order to signal telemetry data in a mitigation efficacy update, it is RECOMMENDED that the DOTS client have already established a DOTS telemetry setup session with the server in 'idle' time. Such a session is primarily meant to assess whether the peer DOTS server supports telemetry extensions and to thus prevent message processing failure (Section 3.1 of [RFC9132]).

An example of an efficacy update with telemetry attributes is depicted in Figure 45.

```

        ]
      }
    ]
  }
}

```

Figure 45: Example of Mitigation Efficacy Update with Telemetry Attributes, Depicted as per Section 5.6

## 9.2. From DOTS Servers to DOTS Clients: Mitigation Status DOTS Telemetry Attributes

The mitigation status telemetry attributes can be signaled from the DOTS server to the DOTS client as part of the periodic mitigation status update (Section 4.4.2 of [RFC9132]). In particular, DOTS clients can receive asynchronous notifications of the attack details from DOTS servers using the Observe Option defined in [RFC7641].

In order to make use of this feature, DOTS clients **MUST** establish a telemetry session with the DOTS server in 'idle' time and **MUST** set the 'server-originated-telemetry' attribute to 'true'.

DOTS servers **MUST NOT** include telemetry attributes in mitigation status updates sent to DOTS clients for telemetry sessions in which the 'server-originated-telemetry' attribute is set to 'false'.

As defined in [RFC8612], the actual mitigation activities can include several countermeasure mechanisms. The DOTS server signals the current operational status of relevant countermeasures. A list of attacks detected by these countermeasures **MAY** also be included. The same attributes as those defined in Section 8.1.5 are applicable for describing the attacks detected and mitigated at the DOTS server domain.

The "ietf-dots-telemetry" YANG module (Section 11.1) augments the 'mitigation-scope' message type defined in the "ietf-dots-signal-channel" module [RFC9132] with telemetry data as depicted in Figure 46.

```

augment-structure /dots-signal:dots-signal/dots-signal:message-type
                  /dots-signal:mitigation-scope/dots-signal:scope:
  +-- (direction)?

```

Figure 47: Response Body of a Mitigation Status with Telemetry Attributes, Depicted as per Section 5.6

DOTS clients can filter out the asynchronous notifications from the DOTS server by indicating one or more Uri-Query options in its GET request. A Uri-Query option can include the following parameters: 'target-prefix', 'target-port', 'target-protocol', 'target-fqdn', 'target-uri', 'alias-name', and 'c' (content) (Section 5.4). The considerations discussed in Section 8.3 MUST be followed to include multiple query values, ranges ('target-port', 'target-protocol'), and wildcard names ('target-fqdn', 'target-uri').

An example of a request to subscribe to asynchronous notifications bound to the "https1" alias is shown in Figure 48.

```

Header: GET (Code=0.01)
Uri-Path: ".well-known"
Uri-Path: "dots"
Uri-Path: "mitigate"
Uri-Path: "cuid=dz6pHjaADkaFTbjr0JGBpw"
Uri-Path: "mid=12332"
Uri-Query: "target-alias=https1"
Observe: 0

```

Figure 48: GET Request to Receive Asynchronous Notifications Filtered Using Uri-Query

If the target query does not match the target of the enclosed 'mid' as maintained by the DOTS server, the latter MUST respond with a 4.04 (Not Found) error Response Code. The DOTS server MUST NOT add a new Observe entry if this query overlaps with an existing Observe entry. In such a case, the DOTS server replies with a 4.09 (Conflict) Response Code.

## 10. Error Handling

A list of common CoAP errors that are implemented by DOTS servers is provided in Section 9 of [RFC9132]. The following additional error cases apply for the telemetry extension:

- \* 4.00 (Bad Request) is returned by the DOTS server when the DOTS client has sent a request that violates the DOTS telemetry extension.
- \* 4.04 (Not Found) is returned by the DOTS server when the DOTS client is requesting a 'tsid' or 'tmid' that is not valid.
- \* 4.00 (Bad Request) is returned by the DOTS server when the DOTS

client has sent a request with invalid query types (e.g., not supported, malformed).

- \* 4.04 (Not Found) is returned by the DOTS server when the DOTS client has sent a request with a target query that does not match the target of the enclosed 'mid' as maintained by the DOTS server.

As indicated in Section 9 of [RFC9132], an additional plaintext diagnostic payload (Section 5.5.2 of [RFC7252]) to help with troubleshooting is returned in the body of the response.

## 11. YANG Modules

### 11.1. DOTS Signal Channel Telemetry YANG Module

This module uses types defined in [RFC6991] and [RFC8345]. It also reuses a grouping from [RFC8783].

```
<CODE BEGINS> file "ietf-dots-telemetry@2022-06-20.yang"
module ietf-dots-telemetry {
  yang-version 1.1;
  namespace "urn:ietf:params:xml:ns:yang:ietf-dots-telemetry";
  prefix dots-telemetry;

  import ietf-dots-signal-channel {
    prefix dots-signal;
    reference
      "RFC 9132: Distributed Denial-of-Service Open Threat
        Signaling (DOTS) Signal Channel Specification";
  }
  import ietf-dots-data-channel {
    prefix data-channel;
    reference
      "RFC 8783: Distributed Denial-of-Service Open Threat
        Signaling (DOTS) Data Channel Specification";
  }
  import ietf-yang-types {
    prefix yang;
    reference
      "RFC 6991: Common YANG Data Types, Section 3";
  }
  import ietf-inet-types {
    prefix inet;
    reference
      "RFC 6991: Common YANG Data Types, Section 4";
  }
  import ietf-network-topology {

Table 4: Registered DOTS Signal Channel CBOR Key Values

### 13.2. DOTS Signal Channel Conflict Cause Codes

Per this document, IANA has assigned a new code from the "DOTS Signal Channel Conflict Cause Codes" registry [Cause].

Code	Label	Description	Reference
5	overlapping-pipes	Overlapping pipe scope	RFC 9244

Table 5: Registered DOTS Signal Channel Conflict Cause Code

### 13.3. DOTS Telemetry URIs and YANG Module Registrations

Per this document, IANA has registered the following URIs in the "ns" subregistry within the "IETF XML Registry" [RFC3688]:

URI: urn:ietf:params:xml:ns:yang:ietf-dots-telemetry  
Registrant Contact: The IESG.  
XML: N/A; the requested URI is an XML namespace.

URI: urn:ietf:params:xml:ns:yang:ietf-dots-mapping  
Registrant Contact: The IESG.  
XML: N/A; the requested URI is an XML namespace.

Per this document, IANA has registered the following YANG modules in the "YANG Module Names" subregistry [RFC6020] within the "YANG Parameters" registry.

Name: ietf-dots-telemetry  
Namespace: urn:ietf:params:xml:ns:yang:ietf-dots-telemetry  
Maintained by IANA: N  
Prefix: dots-telemetry  
Reference: RFC 9244

Name: ietf-dots-mapping  
Namespace: urn:ietf:params:xml:ns:yang:ietf-dots-mapping  
Maintained by IANA: N  
Prefix: dots-mapping  
Reference: RFC 9244

## 14. Security Considerations

### 14.1. DOTS Signal Channel Telemetry

The security considerations for the DOTS signal channel protocol are discussed in Section 11 of [RFC9132]. The following discusses the security considerations that are specific to the DOTS signal channel extension defined in this document.

The DOTS telemetry information includes DOTS client network topology, DOTS client domain pipe capacity, normal traffic baseline and connection capacity, and threat and mitigation information. Such information is sensitive; it MUST be protected at rest by the DOTS server domain to prevent data leakage. Note that sharing this sensitive data with a trusted DOTS server does not introduce any new significant considerations other than the need for the aforementioned protection. Such a DOTS server is already trusted to have access to that kind of information by being in the position to observe and mitigate attacks.

DOTS clients are typically considered to be trusted devices by the DOTS client domain. DOTS clients may be co-located on network security services (e.g., firewall devices), and a compromised security service potentially can do a lot more damage to the network than just the DOTS client component. This assumption differs from the often-held view (often referred to as the "zero-trust model") that devices are untrusted. A compromised DOTS client can send fake DOTS telemetry data to a DOTS server to mislead the DOTS server. This attack can be prevented by monitoring and auditing DOTS clients to detect misbehavior and to deter misuse, and by only authorizing the DOTS client to convey DOTS telemetry information for specific

target resources (e.g., an application server is authorized to exchange DOTS telemetry for its IP addresses but a DDoS mitigator can exchange DOTS telemetry for any target resource in the network). As a reminder, this is a variation of dealing with compromised DOTS clients as discussed in Section 11 of [RFC9132].

DOTS servers must be capable of defending themselves against DoS attacks from compromised DOTS clients. The following non-comprehensive list of mitigation techniques can be used by a DOTS server to handle misbehaving DOTS clients:

- \* The probing rate (defined in Section 4.5 of [RFC9132]) can be used to limit the average data rate to the DOTS server.
- \* Rate-limiting DOTS telemetry, including packets with new 'tmid' values from the same DOTS client, defends against DoS attacks that would result in varying the 'tmid' to exhaust DOTS server resources. Likewise, the DOTS server can enforce a quota and time limit on the number of active pre-or-ongoing-mitigation telemetry data items (identified by 'tmid') from the DOTS client.

Note also that the telemetry notification interval may be used to rate-limit the pre-or-ongoing-mitigation telemetry notifications received by a DOTS client domain.

## 14.2. Vendor Attack Mapping

The security considerations for the DOTS data channel protocol are discussed in Section 10 of [RFC8783]. The following discusses the security considerations that are specific to the DOTS data channel extension defined in this document.

All data nodes defined in the YANG module specified in Section 11.2 that can be created, modified, and deleted (i.e., config true, which is the default) are considered sensitive. Write operations to these data nodes without proper protection can have a negative effect on network operations. Appropriate security measures are recommended to prevent illegitimate users from invoking DOTS data channel primitives as discussed in [RFC8783]. Nevertheless, an attacker who can access a DOTS client is technically capable of undertaking various attacks, such as:

- \* Communicating invalid attack mapping details to the server ('/data-channel:dots-data/data-channel:dots-client/dots-telemetry:vendor-mapping'), which will mislead the server when correlating attack details.

Some of the readable data nodes in the YANG module specified in Section 11.2 may be considered sensitive. It is thus important to control read access to these data nodes. These are the data nodes and their sensitivity:

- \* '/data-channel:dots-data/data-channel:dots-client/dots-telemetry:vendor-mapping' can be misused to infer the DDoS protection technology deployed in a DOTS client domain.

- \* `'/data-channel:dots-data/dots-telemetry:vendor-mapping'` can be used by a compromised DOTS client to leak the attack detection capabilities of the DOTS server. This is a variation of the compromised DOTS client attacks discussed in Section 14.1.
