Traffic Engineering Link Management Information Base

Status of This Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes managed objects for modeling TE links as described in the Link Bundling in MPLS Traffic Engineering (TE) document.

1. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [RFC3410].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIV2, which is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].

2. Introduction

OSPF [RFC3630], Generalized MPLS (GMPLS) [RFC3471], and the Link Management Protocol (LMP) [RFC4204] use the concept of traffic engineering (TE) links to abstract link properties. The effect of this approach is a reduction in the amount of routing information exchanged in the network, which improves routing scalability. In addition, the use of TE links allows the implementation of new capabilities such as link protection.

In this document, we present a MIB module that can be used to manage TE links and their extension, the bundled link. This MIB module enables both the configuration and the performance monitoring of TE links and the bundled link.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

3. Terminology

This document uses terminology from the documents describing link bundling [RFC4201] and GMPLS [RFC3945].

The link bundling feature is designed to aggregate one or more similar entities between a node pair into a bundled link [RFC4201]. In RFC 4201, those entities are referred to as TE links. A TE link is a subinterface capable of carrying MPLS traffic engineered traffic. A TE Link may be comprised of only one underlying component link. In cases where more than one component links are to be combined, multiple component links should be created with differing priorities to indicate hot-standby or parallel utilization.

A bundled link is another kind of Traffic Engineering (TE) link (see [RFC4203]). A link bundle is a subinterface that binds the traffic of a group of one or more TE links. There should be more than one TE Link in a link bundle, but this is not a requirement. Furthermore, if there are more than one TE links in a link bundle at some time, and at some point later, all but one of the links are deleted, the agent may choose to either delete the link bundle, or it may choose to leave it intact. Traffic counters on a link bundle are cumulative for all subinterfaces that it binds together.

4. Feature Checklist

The TE Link MIB module (TE-LINK-STD-MIB) is designed to satisfy the following requirements and constraints:

- The MIB module supports the management of TE links, including bundled links.
- Support is provided for configuration of traffic engineering parameters associated with TE links.
- The MIB module is used to monitor the priority-based component link and TE link bandwidth values.

5. Outline

Configuring bundled links involves the following steps:

- Creating a bundled link.
- Creating TE links.
- Optionally specifying the shared risk link groups associated with the TE links.
- Configuring the component links including the bandwidth parameters and associating the component links with the appropriate TE link.
- Associating the TE links with the appropriate bundled link.

6. Brief Description of MIB Objects

Sections 6.1 - 6.4 describe objects pertaining to TE links while Sections 6.5 - 6.7 describe objects pertaining to component links. The MIB objects were derived from the link bundling document [RFC4201].

6.1. teLinkTable

This table represents the TE links, including bundled links, and their generic traffic engineering parameters.

6.2. teLinkDescriptorTable

This table represents the TE link interface switching capability descriptors.

6.3. teLinkSrlgTable

This table represents the shared risk link groups (SRLGs) associated with TE links.

6.4. teLinkBandwidthTable

This table specifies the priority-based bandwidth traffic engineering parameters associated with TE links.

6.5. componentLinkTable

This table enumerates the component links and their generic traffic engineering parameters.

6.6. componentLinkDescriptorTable

This table enumerates the interface switching capability descriptors that each component link supports.

6.7. componentLinkBandwidthTable

The component link bandwidth table specifies the priority-based bandwidth values associated with the component links.

Component links that belong to the same TE link must be compatible. If these two tables are managed independently, mechanisms should be put in place to ensure consistency between the two tables. TE links that form a bundled link must have compatible traffic engineering parameters (resource class, link metric, and protection type).

The link descriptors of the teLinkDescriptorTable can be derived from the link descriptors of the componentLinkDescrTable.

Some of the bandwidth parameters of the teLinkTable, teLinkDescriptorTable, teLinkBandwidthTable are derived from the bandwidth parameters of the componentLinkTable, componentLinkDescriptorTable, and componentLinkBandwidthTable (maximum reservable bandwidth, minimum LSP bandwidth, maximum LSP bandwidth at specified priority, and unreserved bandwidth).

7. Example of Bundled Link Setup

In this section, we provide a brief example of using the MIB objects described in section 10 to set up a bundled link. While this example is not meant to illustrate every nuance of the MIB module, it is intended as an aid to understanding some of the key concepts. It is meant to be read after going through the MIB module itself. Section

8.2 provides more details on the use of the ifStackTable to establish relationships between bundled links, TE links, and component links.

Suppose that one would like to manually create a bundled link out of two 1:1 TE links, as depicted in the figure in Section 8.2. Assume that the bundled link is associated with SRLGs 10 and 50. Finally, let the component links be port entity interfaces (lambdas). The following example illustrates which rows and corresponding objects might be created to accomplish this.

First, a bundled link entry is created. An ifEntry with the same ifIndex and with ifType teLink needs to be created beforehand.

In teLinkTable:

```
{
    ifIndex                = 2,
    teLinkAddressType       = unknown(0),
    teLinkLocalIpAddr      = 'H',
    teLinkRemoteIpAddr     = 'H',
    teLinkMetric            = 5,
    teLinkProtectionType    = dedicated1For1(4),
    teLinkWorkingPriority   = 7,
    teLinkResourceClass     = 3,
    teLinkIncomingIfId      = 0,
    teLinkOutgoingIfId     = 2,
    teLinkRowStatus         = createAndGo(4),
    teLinkStorageType       = nonVolatile(3)
}
```

In ifStackTable:

```
{
    ifStackHigherLayer      = 0,
    ifStackLowerLayer       = 2,
    ifStackStatus           = createAndGo(4)
}
```

Next, the two TE links are created.

In teLinkTable:

```
{
    ifIndex                = 3,
    teLinkAddressType       = unknown(0),
    teLinkLocalIpAddr      = 'H',
    teLinkRemoteIpAddr     = 'H',
    teLinkMetric            = 5,
    teLinkProtectionType    = unprotected(2),
    teLinkWorkingPriority   = 7,
    teLinkResourceClass     = 3,
}
```

```

    teLinkIncomingIfId          = 0,
    teLinkOutgoingIfId          = 3,
    teLinkRowStatus              = createAndGo(4),
    teLinkStorageType            = nonVolatile(3)
}

In ifStackTable:
{
    ifStackHigherLayer          = 2,
    ifStackLowerLayer           = 3,
    ifStackStatus               = createAndGo(4)
}

In teLinkTable:
{
    ifIndex                     = 4,
    teLinkAddressType           = unknown(0),
    teLinkLocalIpAddr           = 'H',
    teLinkRemoteIpAddr          = 'H',
    teLinkMetric                 = 5,
    teLinkProtectionType        = unprotected(2),
    teLinkWorkingPriority        = 7,
    teLinkResourceClass          = 3,
    teLinkIncomingIfId          = 0,
    teLinkOutgoingIfId          = 4,
    teLinkRowStatus              = createAndGo(4),
    teLinkStorageType            = nonVolatile(3)
}

In ifStackTable:
{
    ifStackHigherLayer          = 2,
    ifStackLowerLayer           = 4,
    ifStackStatus               = createAndGo(4)
}

```

We assign SRLGs to the TE links.

```

In the teLinkSrlgTable:
{
    ifIndex                     = 3,
    teLinkSrlg                  = 10,
    teLinkSrlgRowStatus          = createAndGo(4),
    teLinkSrlgStorageType        = nonVolatile(3)
}

In the teLinkSrlgTable:
{

```

```
        ifIndex                = 4,  
        teLinkSrlg              = 50,  
        teLinkSrlgRowStatus     = createAndGo(4),  
        teLinkSrlgStorageType   = nonVolatile(3)  
    }
```

The bundled link inherits the SRLG properties from the associated TE links.

Next, for each unbundled TE link, a component link is created. An ifEntry with the same ifIndex needs to be created beforehand.

```
In componentLinkTable:  
{  
    ifIndex                = 5,  
    componentLinkPreferredProtection = primary(1),  
    componentLinkRowStatus     = createAndGo(4),  
    componentLinkStorageType   = nonVolatile(3)  
}
```

```
In ifStackTable:  
{  
    ifStackHigherLayer      = 3,  
    ifStackLowerLayer       = 5,  
    ifStackStatus           = createAndGo(4)  
}
```

```
In componentLinkTable:  
{  
    ifIndex                = 6,  
    componentLinkPreferredProtection = secondary(2),  
    componentLinkRowStatus     = createAndGo(4),  
    componentLinkStorageType   = nonVolatile(3)  
}
```

```
In ifStackTable:  
{  
    ifStackHigherLayer      = 4,  
    ifStackLowerLayer       = 6,  
    ifStackStatus           = createAndGo(4)  
}
```

In this example, once a component link is added to the componentLinkTable, the associated link descriptors are implicitly added to the componentLinkDescriptorTable.

TE link link descriptors are derived from their component link descriptors.

Note that the bandwidth attributes in `teLinkDescriptorTable`, `componentLinkDescriptorTable`, `teLinkBandwidthTable`, and `componentLinkBandwidthTable` are maintained by the device according to LSP creation/deletion at different priorities. The values in the `teLinkBandwidthTable` are an aggregation of the values for the component links of the TE links and the TE links of the bundled link.

8. Application of the Interfaces Group to TE Links

The Interfaces Group [RFC2863] defines generic managed objects for managing interfaces. This memo contains the media-specific extensions to the Interfaces Group for managing TE Link interfaces as logical interfaces.

This memo assumes the interpretation of the Interfaces Group to be in accordance with [RFC2863], which states that the interfaces table (`ifTable`) contains information on the managed resource's interfaces and that each sub-layer below the internetwork layer of a network interface is considered an interface. Thus, the TE Link interface is represented as an entry in the `ifTable`. The interrelation of entries in the `ifTable` is defined by Interfaces Stack Group, as defined in [RFC2863].

When using TE Link interfaces, the interface stack table might appear as follows:

```
+-----+
| TE link-interface ifType = teLink(200) +
+-----+
| Underlying Layer...                  +
+-----+
```

In the above diagram, "Underlying Layer..." refers to the `ifIndex` of any interface type, which has been defined for TE Link interworking. Examples include ATM, Frame Relay, Ethernet, etc.

8.1. Support of the TE Link Layer by `ifTable`

Some specific interpretations of `ifTable` for the TE Link layer follow.

Object	Use for the TE Link layer
<code>ifIndex</code>	Each TE Link interface is represented by an <code>ifEntry</code> .
<code>ifDescr</code>	Description of the TE Link interface.

ifType	The value that is allocated for TE Link is 200 [IANAifType].
ifSpeed	The total bandwidth in bits per second for use by the TE Link layer.
ifPhysAddress	Unused.
ifAdminStatus	This variable indicates the administrator's intent as to whether TE Link should be enabled, disabled, or running in some diagnostic testing mode on this interface. Also see [RFC2863].
ifOperStatus	This value reflects the actual or operational status of the TE Link on this interface.
ifLastChange	See [RFC2863].
ifInOctets	The number of received octets over the interface, i.e., the number of received octets in all component links associated with the interface.
ifOutOctets	The number of transmitted octets over the interface, i.e., the number of octets transmitted over all component links associated with the interface.
ifInErrors	The number of packets dropped due to uncorrectable errors.
ifInUnknownProtos	The number of received packets discarded during packet header validation.
ifOutErrors	See [RFC2863].
ifName	Textual name (unique on this system) of the interface, or an octet string of zero length.
ifLinkUpDownTrapEnable	Default is disabled (2).
ifConnectorPresent	Set to false (2).
ifHighSpeed	See [RFC2863].

ifHCInOctets The 64-bit version of ifInOctets; supported if required by the compliance statements in [RFC2863].

ifHCOctets The 64-bit version of ifOutOctets; supported if required by the compliance statements in [RFC2863].

ifAlias The non-volatile 'alias' name for the interface, as specified by a network manager.

ifCounterDiscontinuityTime
See [RFC2863].

Support for ifInOctets, ifOutOctets, ifInErrors, ifInUnknownProtos, ifOutErrors, ifHCInOctets, and ifHCOctets objects is not required if the encoding type is clear. For other encoding types, traffic counters on a TE link are cumulative for all subinterfaces that it binds together.

8.2. Using ifStackTable

This section describes, by example, how to use the ifStackTable to represent the relationship of TE links with underlying TE-enabled interfaces. Implementors of the stack table for TE link interfaces should look at the appropriate RFC for the service being stacked on TE links. The examples given below are for illustration purposes only.

Example: MPLS is being carried on a bundled TE link. The bundled TE link represents a 1:1 optical transport interface.

In this example, the component link is a TE link. The two component links/TE links are grouped in a bundled link.

+-----+-----+-----+-----+	
MPLS interface ifType = mpls(166) ifIndex = 1	
+-----+-----+-----+-----+	
TE link (bundled link) ifType = teLink(200) ifIndex = 2	
+-----+-----+-----+-----+	
TE link ifType = teLink(200) ifIndex = 3	TE link ifType = teLink(200) ifIndex = 4
+-----+-----+-----+-----+	
Component link ifType = opticalTransport(196) ifIndex = 5	Component link ifType = opticalTransport(196) ifIndex = 6
+-----+-----+-----+-----+	

The assignment of the index values could, for example, be:

ifIndex	Description	
1	mpls	(type 166)
2	teLink	(type 200)
3	teLink	(type 200)
4	teLink	(type 200)
5	opticalTransport	(type 196)
6	opticalTransport	(type 196)

The ifStackTable is then used to show the relationships between the various interfaces.

ifStackTable Entries

HigherLayer	LowerLayer
0	1
1	2
2	3
2	4
3	5
4	6
5	0
6	0

In the case where MPLS is using a single TE link, then the upper TE link layer (link bundle) is not required.

```

+-----+
| MPLS interface ifType = mpls(166) |
+-----+
| TE link ifType = teLink(200)      |
+-----+
| Component link                     |
| ifType = opticalTransport(196)    |
+-----+

```

The assignment of the index values could for example be:

ifIndex	Description	
1	mpls	(type 166)
2	teLink	(type 200)
3	opticalTransport	(type 196)

The ifStackTable is then used to show the relationships between the various interfaces.

ifStackTable Entries

HigherLayer	LowerLayer
0	1
1	2
2	3
3	0

8.3. Applicability of ifRcvAddressTable

TE link interfaces are logical interfaces with no media-level addresses. As such, the ifRcvAddressTable is not applicable to these interfaces.

9. TE Link MIB Module Definitions

```
TE-LINK-STD-MIB DEFINITIONS ::= BEGIN

10. Security Considerations

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations. These are the tables and objects and their sensitivity/vulnerability:

- All the tables in this MIB module have routing information in them, so they all have the same security attributes. Unauthorized changes to attributes of these tables can disrupt resource allocation in the network.

Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP. These are the tables and objects and their sensitivity/vulnerability:

- IP address entries in the teLinkTable (teLinkLocalIpAddress and teLinkRemoteIpAddress) may reveal the internals of a network provider IP address space.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPsec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

It is RECOMMENDED that implementers consider the security features as provided by the SNMPv3 framework (see [RFC3410], section 8), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of this MIB module is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.

13. IANA Considerations

The following "IANA Considerations" subsection requests IANA for a new assignment. New assignments can only be made via Standards Action as specified in [RFC2434].

13.1. IANA Considerations for the TE-LINK-STD-MIB

The TE-LINK-STD-MIB should be rooted under the transmission subtree. The IANA has assigned { transmission 200 } to the TE-LINK-STD-MIB module specified in this document.

Information on the procedures with respect to rights in RFC documents can be found in BCP 78 and BCP 79.

Copies of IPR disclosures made to the IETF Secretariat and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementers or users of this specification can be obtained from the IETF on-line IPR repository at <http://www.ietf.org/ipr>.

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights that may cover technology that may be required to implement this standard. Please address the information to the IETF at ietf-ipr@ietf.org.
